2

## Cellular Concept

---

- Optimize the operation of low-power radios spread out over the geographical area
- Cell: service area where a group of mobiles or terminals (referred to as users) are served *primarily*<sup>1</sup> by one basestation – usually located at the centre of the cell
- Cell radius depends on the propagation conditions and the network design – ranges from few meters for indoor or microcellular networks to 10s of kilometers of rural service areas

1. As we will see, there can be situations where a mobile is served by more than one basestation

## Cellular Concept

---

- A basestation/network provides service for users by coordinating access (time slots, frequency channels, or codes) to channels
- Bandwidth (channels) is (are) split amongst a group of cells – called cluster
  - Cluster is repeated to cover a wider geographical area
- Radio coverage is irregular – depending on terrain – first order approximation is the use of hexagonal cells

## Cell Shape

- Radio coverage is irregular – depending on terrain – first order approximation is the use of hexagonal cells
- Other shapes (circular, squares) may be used depending on the intended purpose
  - E.g. indoor networks may assume squares/rectangular

coverage in practice

3/24/2003

ideal coverage for omni-directional antenna at the BTS

Dr. Ashraf S. Hasan Mahmoud

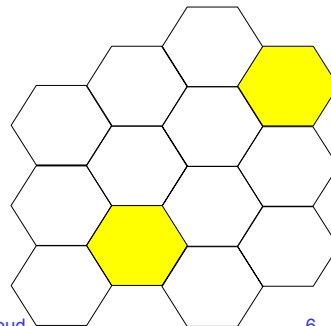

shape used for design - mostly

5

## Cellular Design – Frequency Reuse

- If service area is divided into cells as shown, then it is desirable to use one set channels in more than one cell → Reuse Concept
- This would increase utilization and overall capacity
- Network design should also take into consideration “co-channel” interference
- Too much reuse may lead to unacceptable signal quality → deteriorating capacity
- Function of distance or “Reuse Factor” and communication technology

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

6

## Frequency Reuse Factor of 1

- One set of channel is used in every cell
- Interference is expected to be high
- Distance between co-channel cells equal to

$$D = \sqrt{3}R$$

cluster made of 1 cell

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

7

## Frequency Reuse Factor of 3

- One set of channel is used in every cell
- Interference is expected to be high
- Distance between co-channel cells equal to

$$D = 3R$$

cluster made of 3 cells

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

8

# Frequency Reuse Factor of 7

**Example:**

Interference is expected to be high

- Distance between co-channel cells equal to

$$D = \sqrt{21}R$$

- F1
- F2
- F3
- F4
- F5
- F6
- F7

# Cluster Size and Reuse Distance

- The reuse distance D is given by

$$D = \sqrt{3NR} \quad N = i^2 + j^2 + ij \quad i, j = 0,1,2,3,\dots$$

N is the cluster size

i	j	N	D/R
1	0	1	sqrt(3)=1.7
	1	3	3
2	0	4	2Xsqrt(3)=3.46
	1	7	sqrt(21)=4.6
3	0	9	3Xsqrt(3)=5.19
	1	13	sqrt(39)=6.25

## Co-channel Interference Ratio

- Distance between co-channel cells
- For example for a reuse factor of 7 (in figure):
  - $N = 7$
  - $D = \sqrt{3XN}R = \sqrt{21}R$
  - $q = \sqrt{21} = 4.58$

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

11

## Co-channel Interference Ratio – cont'd

- The signal quality is measure as the ratio of the desired signal power to the total interference power
- Referred to SIR (or SNR)

$$\frac{S}{I} = \frac{S}{\sum_{\forall k} I_k}$$

where  $S$  is the desired signal power (power received from the *home* basestation), and  $I$  is the total interference power

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

12

## 1<sup>st</sup> Tier of Co-channel Interferers

- 6 interferers (downlink analysis)
- Each at distance of  $D/R = \sqrt{3N}$
- SIR is given by

$$\frac{S}{I} = \frac{S}{\sum_{k=1}^6 I_k}$$

- But the power,  $P_r$ , received at a distance  $d$  is given by

$$P_r = \frac{P_0}{d^\alpha}$$

where  $\alpha$  is the path-loss exponent

- Therefore the SIR is given by  $\frac{S}{I} = \frac{1}{\sum_{k=1}^6 \left(\frac{D_k}{R}\right)^{-\alpha}}$

## 1<sup>st</sup> Tier of Co-channel Interferers – cont'd

- If we make the assumption that  $D_k \approx D$  for all  $k$ , then SIR can be written as

$$\frac{S}{I} = \frac{1}{\sum_{k=1}^6 (q)^{-\alpha}} = \frac{q^\alpha}{6}$$

## Example 1:

- For AMPS (using analog FM) uses an SIR level of 18 dB. Calculate the reuse frequency factor – Assume a path-loss exponent of 4

- Solution: SIR = 18 dB or 63.1 (on the linear scale)  
Using the previous equation, the reuse ratio is given by

$$q = 6 \left( \frac{S}{I} \right)^{\frac{1}{\alpha}}$$

Or  $q = 4.41$  and the reuse frequency factor  $N$  is given by

$$N = \frac{q^2}{3}$$

Or  $6.49 \approx 7$

## Example 2:

- Consider a cellular system with 395 total allocated voice channel frequencies. If the traffic is uniform with an average call holding time of 120 seconds and the call blocking during the system busy hour is 2%, calculate
  - a) The number of calls per cell site per hour
  - b) The mean SIR for cell reuse factors equal to 4, 7, and 12

Assume omni-directional antennas with six interferers in the first tier and a slope for the path-loss of 40 dB/decade

## Example 2: cont'd

- Solution:

For a reuse factor of  $N = 4$ , the number of channels per cell is equal to  $395/4 \approx 99$  channels

Using Erlang's B formula (tables) for 99 channels and 2% blocking  
 → traffic load = 87 Erlangs

$$\text{Since } \frac{\text{No of calls per cell site per hour} \times 120}{3,600} = 87$$

therefore, the no of calls per cell site per hour =  $87 \times 30 = 2,610$

$q = \sqrt{3XN} = 3.5$  and  $\text{SIR} = q^6/6 = 25$  or 14 dB

## Example 2: cont'd

- Solution: cont'd

Repeating the calculations for  $N = 7$  and  $N = 12$ , we can write the following table

N	q	Voice Channels per Cell	Calls per Cell per Hour	Mean SIR (dB)
4	3.5	99	2610	14.0
7	4.6	56	1376	18.7
12	6.0	33	739	23.3

72% reduction

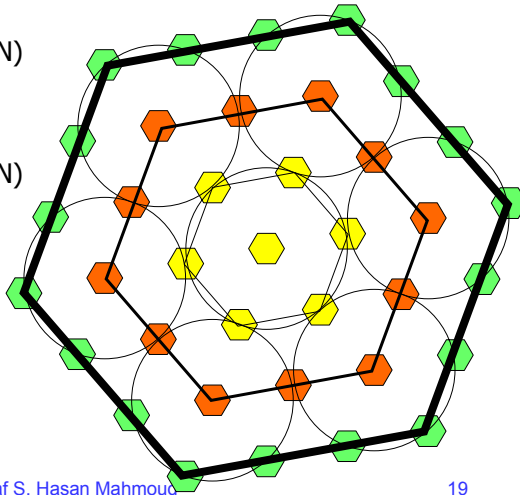

66.4% increase

You can note that by increasing  $N$ , the SIR is improving, however, the call capacity of the cell site is reduced!!

## 2<sup>nd</sup>/3<sup>rd</sup> Tiers of Co-channel Interferers

---

- 2<sup>nd</sup> tier of interferers:
  - 12 interferers
  - Each at distance  $2X\sqrt{3N}$
- 3<sup>rd</sup> tier of interferers:
  - 18 interferers
  - Each at distance  $3X\sqrt{3N}$

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

19

## Exercises

---

- Derive an expression for SIR taking into account the 2<sup>nd</sup> tier of co-channel interferers – Quantify the effect on SIR value of adding the 2<sup>nd</sup> tier to the formula
- Derive an expression for SIR taking into effect the interferences contributed by the first T (T = 1, 2, 3, and 4) tiers. – plot the SIR curves versus the path-loss exponent (let  $\alpha$  range from 2 to 6 in steps of 0.2)

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

20

## Worst Case Scenario

- Mobile of interest is at the edge of the cell
  - Distance of R from cell centre
- Distances from other interfering cells is as shown

$$\frac{S}{I} = \frac{R^{-\alpha}}{2(D-R)^{-\alpha} + 2D^{-\alpha} + 2(D+R)^{-\alpha}}$$

- Writing this in terms of the reuse ratio
 
$$\frac{S}{I} = \frac{1}{2[(q-1)^{-\alpha} + q^{-\alpha} + (q+1)^{-\alpha}]}$$
- Example: For AMPS: N = 7, a = 4, SIR using the above formula is 17.3 dB (lower than previously estimated)

## Directional Antennas

- 3 Sectors case
  - Each sector is assigned a set of channels
- No of interferers = 2 per sector
- SIR is given by  $\frac{S}{I} = \frac{1}{q^{-\alpha} + (q+0.7)^{-\alpha}}$

- Example: For AMPS: N = 7,  $\alpha = 4$

With 3 sectors per cell, SIR is equal to 24.5 dB (about 7 dBs higher the omni-directional case)

## Directional Antennas – cont'd

- 6 Sectors case
  - Each sector is assigned a set of channels
- No of interferers = 1 per sector
- SIR is given by  $\frac{S}{I} = \frac{1}{(q+0.7)^{-\alpha}}$

- Example: For AMPS:  $N = 7$ ,  $\alpha = 4$

With 6 sectors per cell, SIR is equal to 29 dB (about 11 dBs higher the omni-directional case)

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

23

## Erlang-B Model: Revisited

- Erlang-B formula (refer to notes given during second week of semester)

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

24

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

26

## Example 3:

- Compare the spectral efficiency of the digital system (IS-54) with that of the analog system (AMPS) using the following data:
  - The total # of channels is 416
  - The # of control channels = 21 (i.e. 395 channels for voice)
  - The channel bandwidth is 30 kHz
  - The reuse factor,  $N = 7$
  - The total available bandwidth for each direction = 12.5 MHz
  - Coverage area = 10,000 km<sup>2</sup>
  - The required SIR for AMPS = 18 dB (or 63.1)
  - The required SIR for IS-54 = 14 dB (or 25.1)
  - Call blocking = 2.5%

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

27

## Example 3: cont'd

- **Solution:**

*Analog System:*

# of voice channels per cell site =  $395/7 = 56$

The offered traffic load (using Erlang-B tables @ 2% blocking) = 45.6 Erlangs per cell site

The carried load =  $(1-2\%) \times 45.6 = 44.98$  Erlangs / cell site

$$\begin{aligned} \text{Spectral Efficiency} &= \frac{\text{Carried Load} \times \text{No of cell sites}}{\text{Total BW} \times \text{Total Area}} \\ &= \frac{44.98 \times (10,000 / (2.6R^2))}{12.5 \times 10,000} = 1.384 / R^2 \text{ Erlangs/Km}^2/\text{MHz} \end{aligned}$$

*Digital System:*

# of channels per 30 kHz = 3 → # of voice channels per cell site =  $56 \times 3 = 168$

Offered traffic load = 154.5 Erlangs per cell site

Carried traffic load =  $(1-2\%) \times 154.5 = 151.4$  Erlangs per cell site

$$\text{Spectral Efficiency} = \frac{151.4 \times (10,000 / (2.6R^2))}{12.5 \times 10,000} = 7.386 / R^2 \text{ Erlangs/Km}^2/\text{MHz}$$

→ Relative (Digital to Analog) Efficiency =  $7.386 / 1.384 = 5.34$

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

28

## Example 4:

- Consider a cellular system with 395 total allocated voice channels of 30 kHz each. The total available bandwidth in each direction is 12.5 MHz. The traffic is uniform with average call holding time of 120 seconds, and call blocking during the system busy hour is 2%. Calculate:

- The calls per cell site per hour
- The mean SIR
- The spectral efficiency in Erlangs/km<sup>2</sup>/MHz
- The reuse factor,  $N = 7$

For a cell reuse factor of  $N$  equal to 4, 7, and 12, respectively, and for omni-directional, 120°, and 60° systems, calculate the call capacity.

Plot spectral efficiency versus cell radius for  $N = 7$  and comment on the results. Assume that there are 10 mobiles/km<sup>2</sup> with each mobile generating traffic of 0.02 Erlangs. The slope of path loss is  $\alpha = 40$  dB per decade

## Example 4: cont'd

- Solution:**

Considering the first tier of interferers – SIR is given by

Mean SIR =  $1/\sum (q_i^{-\alpha})$  for all interfering  $i$ th co-channel, or

Mean SIR =  $q^{-\alpha}/m$ , assuming  $m$  co-channels all at distance  $D$

In decibels,

$$\text{Mean SIR} = \alpha 10 \log(\text{sqrt}(3N)) - 10 \log m$$

where  $\alpha$  is the path loss component, and

$m$  is the number of interferers ( $m = 6$ , for omni-directional,  $m = 2$  for 120°, and  $m = 1$  for 60°)

The traffic per cell site =  $V \times t \times A_c$

where  $V$  = no of mobile per km<sup>2</sup>

$t$  = traffic in Erlangs per mobile

$A_c$  = area of cell =  $2.6R^2$

→ Therefore traffic per cell site =  $10 \times 0.02 \times 2.6R^2 = 0.52 R^2$

## Example 4: cont'd

- **Solution:** cont'd

$$\text{The spectral efficiency} = \frac{\text{Traffic carried per cell} \times N_c}{\text{Total BW} \times \text{Total Area}}$$

$$= \frac{\text{Traffic carried per cell}}{\text{Total BW} \times 2.6 R^2}$$

For  $N = 7$  and  $120^\circ$  sectorized cell site:

No of voice channels per sector =  $395 / (7 \times 3) = 19$

Offered traffic per sector = 12.3 Erlangs or 36.9 Erlangs per cell site

Carried traffic per cell site =  $(1 - 0.02) \times 36.9 = 36.2$  Erlangs

But carried traffic = No of calls per cell site per hour  $\times 120 / 3600$

→ No of calls per cell site per hour = 1,086

→ Cell radius  $R = \sqrt{36.2 / 0.52} = 8.3$  km

Spectral efficiency =  $36.2 / (2.6 R^2 \times 12.5) = 0.0162$  Erlangs/km<sup>2</sup>/MHz

Mean SIR =  $40 \log \sqrt{3 \times 7} - 10 \log 2 = 23.43$  dB

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

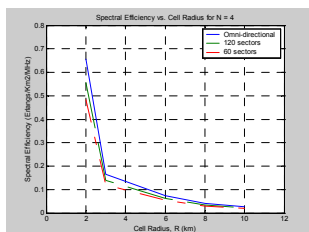

31

## Example 4: cont'd

- **Solution:** cont'd

The previous calculations can be repeated for all other combinations (N, no of sectors)  
Comments:

1. Sectorization reduces co-channel interference and improves mean SIR for a given N. However it reduces trunking efficiency since available channels per sector are fewer. As a result spectral efficiency is lower if N is kept fixed
2. Since a sectorized cellular system has fewer co-channel interferers it is possible to reduce cluster size (N) and hence improve the spectrum efficiency of the overall system
3. If an SIR of 18 dB is required for AMPS to work properly, this can be provided by (N, S) = (7, 1), (4, 3), or (3, 6)

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

32

## Capacity Expansion Techniques

- Use of Directional Antennas (refer to previous slides)
- Cell Splitting
- Lee's Microcell Method
- Overlaid Cells
- Use of Smart Antennas

## Cell Splitting

- Splitting cells into smaller cells and allowing additional channels in the smaller cells:
  - A smaller cell "a" is introduced – half the area of the original cell
  - Channels used in cells "A" are reused in "a" to minimize interference
- Problems & solutions:
  - If the transmit power of "a" is the same as other BSs
  - "a" point of view: SIR is maintained
  - "A" point of view: SIR is increased (reuse distance is decreased by half)
    - Solution1: reduce the power of "a" but SIR for "a" increases!
    - Solution2: channels used within "a" are used in "A" only at distances of less than  $R/2$  → Overlaid cell concept
- Downside of cell splitting:
  - Reduced capacity of the bigger cell
  - Increased handoffs

## Lee's Microcell Method

- Use of direct sectorization leads to reduced trunking efficiency since channels are partitions between different sectors
  - Leads to increased handoffs too
- Lee's microcell:
  - One BS but three zone-sites located at the corners of the cells
  - All three zone-sites act as receivers
  - ONLY one zone-site transmits to the mobile (the BS chooses the one which has best reception from mobile) → LOW interference
- Cluster size can be reduced to 3 from 7 → Capacity increase of 2.33

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

35

## Using Overlaid Cells

- Channels are divided among a larger macrocell that exists with a smaller microcell contained entirely within the macrocell
- Same BS serves both macro- and microcells
- $R_1$  and  $D_1$  are the radius and reuse distance for the macrocells
- $R_2$  and  $D_2$  are the radius and reuse distance for the microcells
- By design:  $D_2/R_2 > D_1/R_1$   
 →  $SIR_{\text{microcells}} > SIR_{\text{macrocells}}$
- Use this increase in system SIR in gaining capacity (e.g. reducing BW requirement)

3/24/2003

Dr. Ashraf S. Hasan Mahmoud

36

## Using Overlaid Cells - Example

- AMPS - underlay network:
  - Channel = 30 kHz, SIR requirement = 18 dB
- AMPS – overlay network:
  - Channel = 15 kHz, SIR requirement = 24 dB
- From the layout:

$$10 \log \frac{\left(\frac{D_2}{R_2}\right)^4}{\left(\frac{D_1}{R_1}\right)^4} = 6 \text{ dB}$$

If  $N = 7$  and  $D_1 = D_2 \rightarrow R_2 = 1/\sqrt{2} R_1$

Therefore, the area for the microcell,  $A_2$ , is half of the area for the macrocell,  $A_1$

$\rightarrow A_2$  and  $A_1 - A_2$  are equal

Let  $M$  be the no of channel available to the overlay and underlay cells, therefore  $15\text{kHz} \times M + 30\text{kHz} \times M = \text{total traffic BW of AMPS} = 395 \times 30\text{kHz} \rightarrow M = 263$

Hence, for a full hexagonal cell, the number of available channels is equal to  $2XM/N = 526/N$  or  $526/395$  134% more channels compared to the non-overlaid network

## Reuse Partitioning

- Channels are divided among larger macrocells and smaller microcells
- BW in both cells remains the same
- Since  $R_2$  (radius for microcells) is less than  $R_1$  (radius for macrocells)  $\rightarrow$  Received signal is better (for the same tx cell site power)  $\rightarrow$  microcells has lower co-channel interference level
- Therefore microcells can employ a smaller frequency reuse factor
- Complexity of BS - handoffs

## Reuse Partitioning - Example

- Underlay-network:  $N_1 = 7 \rightarrow D_1/R_1 = 4.6$  (provides the required SIR = 18 dB)
- For the overlay network, if we deploy  $N_2 = 3$ , then  $D_2 = 3 R_1$  (from geometry)
- But to maintain the required SIR,  $D_2/R_2$  should equal to 4.6, or  $3R_1/R_2 = 4.6 \rightarrow R_2 = 0.652 R_1$
- Distributing the total channels,  $N_c = 395$ , according to area, then the L channels per cell site is given by  
 $N_c = 7X(1-0.652^2)XL + 3X0.652^2XL \rightarrow L = 75$
- Overlay cell uses = 32 channels while the underlay cell uses = 43 channels
- Original AMPS provides  $N_c/7 = 56$  channels per cell site  
 $\rightarrow$  New capacity =  $75/56 = 134\%$

## Smart Antenna

- Users can use same physical channel as long as they are not located in the same region with respect to the BS – referred to as space-division multiple access (SDMA)
- A narrow antenna beam is directed towards the mobile of interest
- Co-channel interference is greatly reduced  $\rightarrow$  reduced frequency factor  $\rightarrow$  increased capacity
- Example:
  - FH-GSM study reported new capacity = 300%
  - CDMA study reported new capacity = 500%
