

Review of Complex Variables

Dr. Samir Al-Amer

Term 002

1 Introduction

The set of complex numbers are numbers that are expressed in the form

$$z = x + jy$$

where x and y are real numbers, x is called the real part¹ of z ($x = Re\{z\}$), y is the imaginary part of z ($y = Im\{z\}$) and $j = \sqrt{-1}$. Using complex numbers allows us to solve the following equation

$$x^2 + 1 = 0$$

which does not have a solution if we restrict x to be a real number.

1.1 Complex Arithmetic:

$$\begin{aligned}j^2 &= -1 \\j^3 &= -j \\j^4 &= 1\end{aligned}$$

If a is a positive real number then

$$\begin{aligned}\sqrt{-a} &= j\sqrt{a} \\ \sqrt{-3}\sqrt{27} &= \sqrt{-81} = j9\end{aligned}$$

$$\begin{aligned}(x + jy) + (u + jv) &= (x + u) + j(y + v) \\(x + jy) - (u + jv) &= (x - u) + j(y - v) \\(x + jy) \times (u + jv) &= (xu - yv) + j(xv + yu) \\ \frac{(x + jy)}{(u + jv)} &= \frac{(xu + yu) + j(yu - xv)}{u^2 + v^2}\end{aligned}$$

¹If $x=0$, z is a real number
if $y=0$ then z is a pure imaginary number

1.2 Conjugate and Modulus

Definition 1 The *conjugate*² of a complex number $z = x + jy$ is defined as $\bar{z} = x - jy$.

Note that

$$\begin{aligned} \operatorname{Re}(z) &= \operatorname{Re}(\bar{z}) \\ \operatorname{Im}(z) &= -\operatorname{Im}(\bar{z}) \\ \operatorname{Re}(z) &= \frac{1}{2}(z + \bar{z}) \\ \operatorname{Im}(z) &= \frac{1}{2}(z - \bar{z}) \\ \overline{\bar{z} + \bar{w}} &= z + w \\ \overline{z \bar{w}} &= \bar{z} w \\ \overline{\bar{z} + w} &= z + \bar{w} \end{aligned}$$

Definition 2 The *modulus*³ of a complex number z is defined as .

$$|z| = |x + jy| = \sqrt{x^2 + y^2}$$

$$\begin{aligned} |z| &= \sqrt{\bar{z}z} \\ |z| &= |\bar{z}| \\ \left| \frac{z}{w} \right| &= \frac{|z|}{|w|} \\ |zw| &= |z| |w| \\ |z + w| &\leq |z| + |w| \quad \text{triangular inequality} \end{aligned}$$

1.3 Polar Form

A complex number can be expressed in different forms: (standard, polar and trigonometric)

²some times the conjugate is denoted by z^*

³also called absolute value or length.

$$\begin{aligned}
z &= x + jy = \rho e^{j\theta} = \rho \cos(\theta) + j\rho \sin(\theta) \\
\rho &= |z| = \sqrt{x^2 + y^2} \\
\theta &= \arg(z) = \tan^{-1}\left(\frac{y}{x}\right) = \tan^{-1}\left(\frac{\text{Im}(z)}{\text{Re}(z)}\right) \\
x &= \rho \cos(\theta) \\
y &= \rho \sin(\theta)
\end{aligned}$$

ρ is the modulus of z and θ is called the argument of z .

Operations in Polar Form:

$$\begin{aligned}
\rho_1 e^{j\theta_1} \rho_2 e^{j\theta_2} &= \rho_1 \rho_2 e^{j(\theta_1 + \theta_2)} \\
\frac{\rho_1 e^{j\theta_1}}{\rho_2 e^{j\theta_2}} &= \frac{\rho_1}{\rho_2} e^{j(\theta_1 - \theta_2)}
\end{aligned}$$

1.3.1 Some useful relationships:

$$\begin{aligned}
j &= 1 \angle \underline{\pi/2} \\
-j &= 1 \angle \underline{-\pi/2} \\
z &= r e^{j\theta} \Rightarrow z^n = r^n e^{jn\theta} = r^n \angle \underline{n\theta}
\end{aligned}$$

Euler Formula

$$\rho e^{j\theta} = \rho \cos(\theta) + j\rho \sin(\theta)$$

DeMoivre Formula

$$(\cos(\theta) + j \sin(\theta))^n = \cos(n\theta) + j \sin(n\theta)$$

$$z = r e^{j\theta} \Rightarrow z^n = r^n e^{jn\theta} = r^n \angle \underline{n\theta}$$

Example 1 Express $4 + j3$ in polar form

$$\begin{aligned}
\rho &= \sqrt{4^2 + 3^2} = 5 \\
\theta &= \tan^{-1}\left(\frac{3}{4}\right) = 36.9^\circ
\end{aligned}$$

Example 2 If $z = 4 + j5$ what is \bar{z}

$$\overline{4 + j5} = 4 - j5$$

If $z = 3e^{j\pi/3}$ what is \bar{z}

$$\overline{3e^{j\pi/3}} = 3e^{-j\pi/3}$$

1.4 The Poles and Zeros

A complex function $F(s)$ is **analytic** in a region if the function and all its derivatives exist in that region. The points at which the function is analytic are called ordinary while points in the s -plane at which the function $F(s)$ are not analytic are called the singular points of $F(s)$. Singular points at which the function $F(s)$ approaches infinity are called the **poles** of $F(s)$. If $F(s)$ is a rational function then the **poles** are the zero of the denominator polynomial. Points at which $F(s)$ equals zero are called the zeros of $F(s)$. Finite **zeros** of a rational function $F(s)$ are the zeros of the numerator polynomial.

Example 3 What are the poles and zeros of the following function

$$F(s) = \frac{s + 2}{(s + 3)(s + 4)}, \quad G(s) = \frac{4}{(s + 2)^2(s + 5)}$$

The functions $F(s)$ has two simple poles (at $s = -3$ and $s = -4$) and one finite zero ($s = -2$). It has another zero at infinity.

$G(s)$ has double poles (repeated poles) at $s = -2$ and a simple pole at $s = -5$ and has no finite zero.

Definition 3 A rational complex function $F(s) = \frac{N(s)}{D(s)}$ is called **proper** if

$$\text{degree}(D(s)) \geq \text{degree}(N(s))$$

It is **strictly proper** if

$$\text{degree}(D(s)) > \text{degree}(N(s))$$
