

## EE200 DIGITAL LOGIC CIRCUIT DESIGN

The material covered in this class will be as follows:

- Binary codes, BCD code, BCD addition
- Other decimal codes
- Gray code
- Error-detecting code (parity bit)
- Alpha-numeric codes, ASCII code

### Binary codes:

- Digital systems and circuits work with signals that have only one of two states corresponding to digital 1 and 0.
- Any discrete element of information among a group of quantities (elements) can be represented by a binary code.
- One bit can represent up to two elements (1 or 0).
- A group of  $2^n$  distinct elements requires a minimum of n bits.
- $\therefore$  to code a group of m elements, we need to use n bits such that:  $2^n \geq m$ .
- Examples:
  - A group of four elements can be represented by two bit code [00, 01, 10, and 11].
  - A binary code to represent the decimal digits [0-9], must contain at least four bits because
$$(2^4=16) \geq 10 \geq (2^3=8).$$

## Decimal Codes:

Decimal Digit	BCD 8421	Excess-3	84-2-1	2421
0	0000	0011	0000	0000
1	0001	0100	0111	0001
2	0010	0101	0110	0010
3	0011	0110	0101	0011
4	0100	0111	0100	0100
5	0101	1000	1011	1011
6	0110	1001	1010	1100
7	0111	1010	1001	1101
8	1000	1011	1000	1110
9	1001	1100	1111	1111

## BCD Addition:

The addition of two BCD digits with a possible carry from the previous less significant pair of digits results in a sum in the range 0 to a maximum of (9+9+1=19). There is a difference in the representation of the sum in binary and in BCD code.

1. If  $0 \leq \text{Sum} \leq 9$  then, sum in BCD = sum in binary,
2. If  $10 \leq \text{Sum} \leq 19$  then, sum in BCD consists of 8 bits which is not equal to the sum in binary. The correction needed in the sum to represent it in BCD is the addition of 6 to the binary sum.

$$\begin{array}{r}
 4 \quad 0100 \quad 4 \quad 0100 \quad 8 \quad 1000 \\
 +5 \quad \underline{0101} \quad +8 \quad \underline{1000} \quad +9 \quad \underline{1001} \\
 \hline
 9 \quad 1001 \quad 12 \quad 1100 \quad +17 \quad 10001 \\
 \hphantom{9 \quad 1001 \quad } +0110 \quad \hphantom{12 \quad } +0110 \\
 \hline
 \hphantom{9 \quad 1001 \quad } 10010 \quad \hphantom{12 \quad } 10111
 \end{array}$$

## Signed BCD Addition

Signed decimal numbers in BCD are represented, in a similar way, to the signed numbers in binary. The plus sign is represented by four zeros and the minus by 1001. An example of signed BCD addition follows:

Add the signed decimal numbers (+375) + (-240) using BCD representation.

Solution:

$$\begin{array}{rcl} +375 & \rightarrow & 0000\ 0011\ 0111\ 0101 \\ +240 & \rightarrow & 0000\ 0010\ 0100\ 0000 \\ -240 & \rightarrow & 1001\ 0111\ 0110\ 0000 \end{array} \quad \text{Add} \quad \begin{array}{r} 0000\ 0011\ 0111\ 0101 \\ + \underline{\hspace{4cm}} \\ 1001\ 1010\ 1101\ 0101 \end{array}$$

Correct the BCD digits by adding 0110 →   
  $\underline{\hspace{4cm}}$   
 1010 0001 0011 0101  
 0110  
  $\underline{\hspace{4cm}}$   
 1 0000 0001 0011 0101

Repeat correction →   
  $\underline{\hspace{4cm}}$   
 1010 0001 0011 0101  
 0110  
  $\underline{\hspace{4cm}}$   
 1 0000 0001 0011 0101

The end carry is discarded and the result is the BCD equivalent of +135

## Error Detection Code:

A common method to achieve error detection in binary information transmission from one location to another is by means of a parity bit. A parity bit is defined as an extra bit included with a message to make the total number of 1's transmitted either odd or even.

	Odd Parity		Even Parity
message	P	message	P
0000	1	0000	0
0001	0	0001	1
0010	0	0010	1
0011	1	0011	0
0100	0	0100	1
0101	1	0101	0
0110	1	0110	0
0111	0	0111	1
1000	0	1000	1
1001	1	1001	0
1010	1	1010	0
1011	0	1011	1
1100	1	1100	0
1101	0	1101	1
1110	0	1110	1
1111	1	1111	0

### Gray Code:

Decimal equivalent	Binary	Gray code
0	0000	0000
1	0001	0001
2	0010	0011
3	0011	0010
4	0100	0110
5	0101	0111
6	0110	0101
7	0111	0100
8	1000	1100
9	1001	1101
10	1010	1111
11	1011	1110
12	1100	1010
13	1101	1011
14	1110	1001
15	1111	1000

### ASCII Code [American Standard Code for Information Interchange]:

- Used for handling numbers, letters, characters...etc.
- This type of code is called alpha-numeric code.
- To handle 10 decimal digits, 26 small letters, 26 capital letters, and at least 20 other characters, the code must cater for at least 82 elements.  $(128=2^7) \geq 82 \geq (64=2^6)$ .
- Therefore we need seven bits for the code.

The ASCII code is given in the following table.

	<b>b<sub>7</sub>b<sub>6</sub>b<sub>5</sub></b>								
<b>b<sub>4</sub>b<sub>3</sub>b<sub>2</sub>b<sub>1</sub></b>	<b>000</b>	<b>001</b>	<b>010</b>	<b>011</b>	<b>100</b>	<b>101</b>	<b>110</b>	<b>111</b>
