

SWE 363: WEB ENGINEERING & DEVELOPMENT

Spring Semester 2015 (2014-2)

Web Architecture – Part 1

Dr. Nasir Al-Darwish

Computer Science Department King Fahd University of Petroleum and Minerals *darwish@kfupm.edu.sa*

Outline

- Introduction to the Internet
 - Definition
 - Hierarchical Structure
 - Internet Protocols
 - Introduction to the Web
 - Definition
 - Web Clients and Servers
 - □ Web Architecture & Operation
 - Websites & Web Documents

What is the Internet?

- A global heterogeneous network that connects millions of computers world wide. It uses TCP/IP protocols for the *network*, *transport* and *application* layers.
- IP (Internet Protocol) is a network-layer protocol that makes it possible to connect (e.g. using a router) two or more networks into one internetwork.
- TCP/IP is designed to work with a multitude of data-link and physical layers (e.g. Ethernet, ATM, FDDI, PPP)

What is the Internet? ...

- The goal is to provide connectivity between computers (hosts) and their users to
 - □ Share resources
 - □ Increase reliability and availability
 - □ Collaborate (email, distributed computing, etc.)
 - □ Access remote information
- Thus, the Internet is a vehicle for transferring data from one computer to another.

Common Internet Applications

- Each Internet end-user application has its own (applicationlayer) protocol.
- The World-Wide Web (WWW); uses HTTP protocol
- Electronic mail (email); uses SMTP/POP/IMAP protocols
- File transfer (e.g. ftp); uses FTP protocol
- Remote login (e.g. telnet)
- Streaming multimedia (e.g. Internet feeds of live audio and video, video on demand (VoD))
- Internet telephony (VoIP), Chatting
- Many others

How the Internet works

How the Internet works

- Source host generates a message & converts it into packets
- Source host or a router may fragment a packet into smaller packets (fragments)
- Packets transferred independently across network
- Destination router delivers packets to the destination host
- Destination host reassembles fragments to build the original packet
- TCP layer of destination host rearranges received packets to build the submitted message

Internet Hierarchical Structure

• To manage the growth (scalability) of the Internet, it is roughly structured in a hierarchical manner

Internet Hierarchical Structure ...

- Internet Service Provider (ISP)
 - International, National, Regional, Local
- At the lowest level are the organizations networks
 - □ e.g. KFUPM network
 - Which can act as ISP for lower-level user networks as well (e.g. home networks or small office networks)
- Two ISP networks can be connected to each other through network access points (NAP) or private peering.
 - NAP: data communication facilities that provide access to higher-speed links
- Routers: networking devices that forward data packets across an internetwork toward their destinations

Layered Architecture

- The operation of the Internet is controlled by software which is functionally structured into layers called TCP/IP protocol stack
- Each layer has a number of protocols to govern and facilitate communication between different devices

Layered Architecture ...

- *Application layer*: acts as an interface for user to allow them to access network resources. Each Internet application has its own application layer protocol.
- Transport layer: provides reliable channel for message delivery and error recovery between applications
- Network layer: moves packets from the source host to the destination host across the network
- Data-link layer: organizes data into frames and move frames from one machine to the next machine of the path to the destination (hop-to-hop delivery)
- *Physical layer*: transmits bits over a medium and provide mechanical and electrical specifications.

Layered Architecture ...

- Each layer adds meta-data (control information) to facilitate communication between corresponding layers at different hosts
- The control data includes address info. (source/destination address of hosts, port numbers (sending/receiving application), error control information, etc.

Addressing

- Each host is identified using a unique global address (called IP address) or hostnames (also a host can be assigned a symbolic name; DNS servers map hostnames to IP addresses)
- Processes on the same host are uniquely identified using the host address (IP address) + the transport layer protocol port number (e.g. a web server is running at TCP port # 80)

The Web

- Also called World Wide Web, WWW, W3; started in 1990s at CERN (European Center for Nuclear Research) by Tim Berners Lee
- Forms an overlay network over the Internet; massive repository of information
- A collection of distributed web documents and other web resources uniquely identified (using URLs), linked to each other, can be accessed via the Internet
- Web documents can have different types of information (multimedia): text, images, audio and video
- Provide a medium to share information; access and interact with remote applications and systems
- Main features: Portability, Scalability, User-Friendly Interface (Accessibility)

Primary Components of the Web

- Web Browser, Web Server, Internet
- Web server (i.e., HTTP server): is the application-layer software that
 - □ Stores a set of Web documents (web pages) and other resources
 - **Constitution** Responds to requests from the browser by sending a copy of the document
 - □ *Examples*: Apache, Microsoft IIS
- Web browser (also called user agent, web client or HTTP client)
 - □ End-user application program that represents the user interface to the Web
 - **□** Fetches information from Web server and displays it to the user
 - □ *Examples*: Mosaic (1993), NN (1994), IE (1995), Mozilla (1998), Firefox (2004), Opera, Safari, many others
- Web standards
 - □ Transfer (delivery) protocol: HyperText Transfer Protocol (HTTP)
 - □ Hypermedia links: Uniform Resource Locator (URL) to identify web resources
 - Document encoding: HTML (HyperText Markup Language), XML (eXtensible Markup Language)

Web Architecture & Operation

- Web pages (documents) are hosted (stored) in computers running special software called <u>web servers</u>
- Web documents can be accessed and viewed using special programs called <u>browsers</u> (web clients or user agents)
- Browsers & Web servers are often running on different computers
- Browsers use <u>HTTP protocol</u> to communicate with the Web servers
- The HTTP protocol is a *command-response protocol*, with commands sent by the client and responses to them sent by the web server

The web is a client-server Internet application

Components of Web Infrastructure

- *Content*: Web Pages expressed in HTML
 - □ HTML contain references to other types of objects such as images
- Clients
 - □ Send requests to Servers / Receive responses
- Servers
 - □ Receive requests from clients / Send responses
 - □ Store or generate the responses
- Proxies
 - Placed between clients and servers
 - Act as a server for the client, and a client to the server
 - Provide extra functions
 - Caching, anonymization, logging, filtering access

Ingredients of Web Implementation

- HTML (HyperText Markup Language): uses markup or tags
 - □ The *anchor* tag is the most important tag (*Why*?)
 - □ In my web page:
 - I work at KFUPM
 - □ It is a Web because *html pages are nodes, the anchor tags are the links*
 - □ From functionality viewpoint, the anchor tag is the most important tag. It is the tag that makes the web a web.
- *URLs* (or more generally, *URIs*)
- HTTP (HyperText Transfer Protocol): Application-Layer protocol used between a web client and a web server

URL Structure

- Uniform Resource Locator (URL)
 - □ Represents the address of a resource on the Web
- A URL defines:
 - Protocol used to access/transfer the document (such as HTTP or FTP; the default is HTTP)
 - □ Server that hosts the document using its domain name (or IP address)
 - □ Protocol port number of the server (optional; the default is 80)
 - Path and document name
- General form of URL

protocol://server.domain-name:port/path-and-file-name

path

```
Example
```

http://www.kfupm.edu.sa/dad/links.html

protocol

Web Operation: Fetching Content

- A user starts a browser on his computer and request a web document by specifying its URL, e.g. http://www.kfupm.edu.sa/
- The browser uses DNS find the web server IP address.
- Then, the browser sends a message to the server requesting the required document
- The server finds the document in its file system and sends it back to the browser
- The browser interprets the content of the document and displays (renders) it for the user
- If the document contains images,
 - □ Images will be on separate files and only their URLs will be embedded in the base document
 - **□** The browser will send a new request for each image file

Website Structure

- A website is made up of a set of related web pages linked to each other; these pages can be on one server or distributed on different servers
- Navigation order
 - □ Linear
 - Web pages are linked in a strict sequence
 - Useful for guided navigation, tutorials, multi-part articles, etc.
- Hierarchical (tree)
 - □ Web pages are arranged hierarchically (also called tree)
 - □ The "root" is the website's homepage
- Hybrid (non-linear)
 - Webpage links can form sequences, trees, loops, or whatever paths are needed
 - □ Might this be confusing to a site visitor?

Linear

- Three primary categories:
 - Static documents
 - Dynamic documents
 - Active documents

- Static documents
 - Fixed-content document created and stored in a server
 - Content is determined when it is first created not when it is used
 - The file contains text and formatting instructions
 - The client cannot change the content of the document
 - □ Use HTML technology

- Static documents
 - Fixed-content document created and stored in a server
 - Content is determined when it is first created not when it is used
 - The file contains text and formatting instructions
 - The client cannot change the content of the document
 - □ Use HTML technology

b. Response

Client

Server

- Dynamic documents
- The requested document does not exist in a predefined format but is created on demand
- The accessed document contains code (application program) that the server executes to generate the document to be submitted to the browser
- Personalized (customized) web pages
- Can access restricted resources on the server such as databases
- □ High load on the server
- Use Common Gateway Interface (CGI) or ASP technologies for server side programming

b. Running the program and creating the document

c. Response

Active documents

- The requested document contains a program; the server submits a copy of the program to the browser; the browser will run the program at the client side
- □ Can interact with user
- Does not create overhead for the server in the same way as dynamic documents
- The client can store the document and run it again and again without making another request
- Can save bandwidth and transmission time
- Use JavaScript language for client side programming

a. Request for a copy of a program

c. Running the program and creating the document

Web Servers Market Share

Apache	63.5%				
Microsoft-IIS	16.7%				
Nginx	14.5%				
LiteSpeed	■ 1.8%				
Google Servers	1.3%				
Tomcat	0.7%				
Lighttpd	0.5%				
IBM Servers	0.3%				
Yahoo Traffic Server	0.2%				
Oracle Servers	0.2%				
Zope	0.1%				
Resin	0.1%				
Zeus	0.1%				
	W3Techs.com, 31 January 2013				
Percentages of websites using various web servers

Web Browser

- Software programs that fetch, interpret and display web pages
- Popular web browsers: <u>Mozilla Firefox</u>, Microsoft <u>Internet Explorer</u> (IE), Apple <u>Safari</u>, <u>Google Chrome</u>, <u>Opera</u>
- Some features: Tabbed Browsing, History Feature, AutoComplete, Favorites, Off-Line Browsing, Viewing source code, Downloading files, Caching, Privacy settings, etc.

Web Browser ...

- Is the client
- Generates HTTP requests
 - User types URL, clicks a hyperlink or bookmark, clicks "reload" or "submit"
 - □ Automatically downloads images referenced in an HTML page
- Submits the requests (fetches content)
 - □ Via one or more HTTP requests
- Presents the response
 - □ Parses HTML and *renders* the Web page
 - □ Invokes helper applications (*e.g.*, Acrobat, RealPlayer)
- Maintains cache
 - □ Stores recently-viewed objects and ensures freshness

Web Browser ...

 Browser settings determine how output will be displayed, how security measures are applied, etc.

Web Browsers – Market Share

Source: http://gs.statcounter.com/#browser-ww-monthly-201112-201212-map

Components of a Web Browser

- 1. User and display interface
- 2. Browser engine, an embeddable component that provides a highlevel interface for querying and manipulating the Rendering Engine;
- 3. Rendering engine, which performs parsing and layout for HTML documents, optionally styled with CSS
- 4. Networking subsystem
- 5. JavaScript interpreter
- 6. XML parser
- 7. Display backend, which provides drawing and windowing primitives, user interface widgets, and fonts
- 8. Data persistence subsystem, which stores various data associated with the browsing session on disk, including bookmarks, cookies, and cache

Cross-Browser Compatibility

- Great diversity of web browsers
 - □ There are hundreds of web browsers (and of varying versions) in use
 - Differ in functionality, performance and supported features for HTML, JavaScript, CSS, etc.
 - A cross-browser compatible Web page will look more or less the same in all of the existing Web browsers
- Cross-browser compatibility is difficult to achieve
 - □ May make Web pages look totally different
 - □ Achieving 100% compatibility with all potential browsers is impossible
- W3C is working toward the goal of a universal client-side platform
 - □ Write clean code that conforms to the www consortium (W3C) standards to get consistent results across different browser platforms
- HTML editors are, on their part, notorious for creating non-compliant and garbage code.
 - □ It is best if you write HTML code directly using a text-editor
 - If you must use an HTML front-end, use Adobe Dreamweaver or MS Visual Studio (2008 or later)
