

Chapter 9

Graphs

Sec. 9.2: Terminology

- Let $G=(V, E)$ be an undirected graph & $e=\{u,v\}$ be an edge, then
 - u and v are adjacent
 - e is incident to u and v
 - u and v are connected
 - u and v are endpoints of e

Definition

- **Degree of a vertex** v in an undirected graph G is denoted by $\deg(v)$ and is defined to be the number of edges incident to it where a loop contributes twice to the degree.

Definition

- If $\deg(v) = 0$ then v is called isolated
- If $\deg(v) = 1$ then v is called pendant

The Hand Shaking Theorem

- Let G be an undirected graph (simple, multi, or pseudo) with e edges. Then

The sum of all degrees = $2e$

$$\sum_v \deg(v) = 2e$$

- Notice that $2e$ is even number

Theorem

- Any undirected graph has an even number of vertices of odd degree
 - ❖ Because
 - the sum of all vertices of even degrees is even
 - The sum of all degrees is even

Definition

- Let G be a directed graph & $e=(u,v)$ be an edge, then
 - u is adjacent to v
 - v is adjacent from u
 - u is initial vertex of e
 - v is terminal (end) vertex of e

Definition

- $\text{In-deg}(v) = \text{deg}^-(v) = \#$ of edges with v as terminal vertex
- $\text{Out-deg}(v) = \text{deg}^+(v) = \#$ of edges with v as initial vertex

Theorem

- Let G be a directed graph, then
The sum of all in-degrees
= the sum of all out-degrees
= total number of edges

$$\sum_{v \in V} \deg^{-}(v) = \sum_{v \in V} \deg^{+}(v) = |E|$$

Special graphs

- Complete graph on n vertices K_n : is a simple graph with all of the $C(n,2)$ edges
- Cycle C_n , $n \geq 3$
- Wheel W_n , $n \geq 3$
- n -Cubes Q_n , $n \geq 1$

Special Graphs

Graph	Vertices	Edges	Degree
K_n	n	$C(n,2)$	$n-1$
C_n	n	n	2
W_n	$n+1$	$2n$	3 and n
Q_n	2^n	$n2^{n-1}$	n

Bipartite Graph

- A simple graph $G=(V,E)$ is a bipartite if $V=V_1 \cup V_2$ and $V_1 \cap V_2 = \emptyset$ such that no edge in E connects two vertices V_1 in or two vertices in V_2 ,
- Note that C_n is bipartite iff n is even

Complete Bipartite Graph

- $K_{m,n}$ is a complete bipartite iff $|V_1|=m$ and $|V_2|=n$ and every vertex in V_1 is connected to every vertex in V_2 and vice versa.

Sec 9.3: Graphs Representations

Sec 8.3: Graphs Representations

- There are two ways to represent graphs
 1. **Adjacency Lists:** each vertex has a linked list that contains vertices adjacent to it.
 2. **Adjacency Matrix:** which is defined as follows

Adjacency Matrix

- For any simple graph G , we have an adjacency matrix $A_G = [a_{ij}]$, where $a_{ij} = 1$, if $\{v_i, v_j\} \in E$, and 0 otherwise.
- Notice that A_G is symmetric if G is simple and for directed graphs it may not be.
- A_G is called sparse if it has few 1s.

Adjacency Matrix

- For multigraphs or pseudographs A_G can be represented by
 $a_{ij} = k$, if there are k edges between v_i and v_j .

Isomorphism

Isomorphism

- Two graphs G_1 & G_2 are **isomorphic** iff there is a bijective function $f : V_1 \rightarrow V_2$ such that whenever
$$\{a,b\} \in E \quad \text{then} \quad \{f(a), f(b)\} \in E.$$
- This means that G_1 can be redrawn to get G_2 with the same number of vertices, edges and degrees.
- See examples in textbook.

Isomorphism

- There are some graphical properties that are invariant (preserved) under isomorphism, e.g.
 - # of vertices
 - # of edges
 - Degrees
 - Cycles
 - Euler cycles
 - Hamilton cycles

Definitions

- A subgraph of $G = (V, E)$ is a graph $H = (U, F)$ such that $U \subseteq V$ and $F \subseteq E$.
- A graph is called **regular** iff every vertex has the same degree.
- A graph is called **n-regular** iff every vertex has $\text{deg} = n$.

Sec. 9.4: Connectivity

Definitons

- A path is sequence of edges $\{a,b\}, \{b,c\}, \{c,d\}, \{d,e\}, \dots$
- The length of a path $e_1, e_2, e_3, e_4, \dots, e_n$ is the number of edges in the path $=n$.
- A path is a circuit (cycle) when it begins and ends with the same vertex and $n>0$.
- The path is said to passes through the vertices a, b, c, \dots Or traverses the edges $e_1, e_2, e_3, e_4, \dots, e_n$

Definition

- A path is **simple** if it doesn't contain the same edge more than once.
- An undirected graph is **connected** iff there is a simple path between any two vertices.
- A directed graph is **strongly connected** iff there is a 2-way path between any two vertices.
- A directed graph is **weakly connected** iff there is a path between any two vertices in its underlying undirected graph.

Definition

- A **cut vertex** in a connected graph is a vertex whose removal produces unconnected graph
- A **cut edge (bridge)** in a connected graph is an edge whose removal produces unconnected graph

Definitions

- The connected components in any graph are the maximum connected subgraphs
- The strongly connected components in any directed graph are the maximum strongly connected subgraphs

Sec. 9.5: Euler and Hamilton Paths and Circuits

Definitions

- Euler path in a graph G is a simple path containing every edge in G .
 - Start from a vertex & walk on every edge exactly once but you don't have to return back to the same vertex
- Euler circuit in a graph G is a simple circuit containing every edge in G .
 - Start from a vertex & walk on every edge exactly once and return back to the same vertex.

Theorem

- A connected multigraph has an Euler circuit iff every vertex has an even degree.
- A connected multigraph has an Euler path but not an Euler circuit iff there exists exactly two vertices of odd degrees and the others are even degrees.

Definition

- A Hamilton path in G is a path that visits every vertex exactly once
- A Hamilton circuit in G is a circuit that visits every vertex exactly once
- Note that every K_n has Hamilton Circuit because it has C_n

Remark

- Some graphs could have Euler path but no circuits and same for Hamiltonian.

Sec 9.7: Planar graphs

Definition

- A graph is called planar if it can be drawn in the plane without any edge crossing. Any planar graph split the plane into regions.
- E.g., K_4 and Q_3 are planar

Euler Formula

- Let G be any connected simple planar graph. Then the number of regions

$$r = |E| - |V| + 2$$

Sec. 9.8: Graph Coloring

Problem

- Color a map of regions with common borders such that no two neighbor regions have the same color.
- Maps can be modeled by a graph called **the dual graph** where
 - Vertices represent regions
 - Edges represent common borders

Definition

- A **coloring** of a simple graph is an assignment of colors of vertices of G such that adjacent vertices are colored with different colors.
- The **chromatic number** of a graph G is the least number of colors needed to color the graph correctly.

The 4 colors Theorem

- The chromatic number of a planar graph ≤ 4 .
- Recall that a graph is called planar if it can be drawn in the plane without any edge crossing.

Examples

- $\chi(K_n) = n$
- $\chi(C_n) = 2$ if n is even and 3 otherwise
- $\chi(W_n) = 3$ if n is even and 4 otherwise

Chapter 10: Trees

Definition

- A tree is a connected undirected acyclic (with no cycle) simple graph
- A collection of trees is called forest.

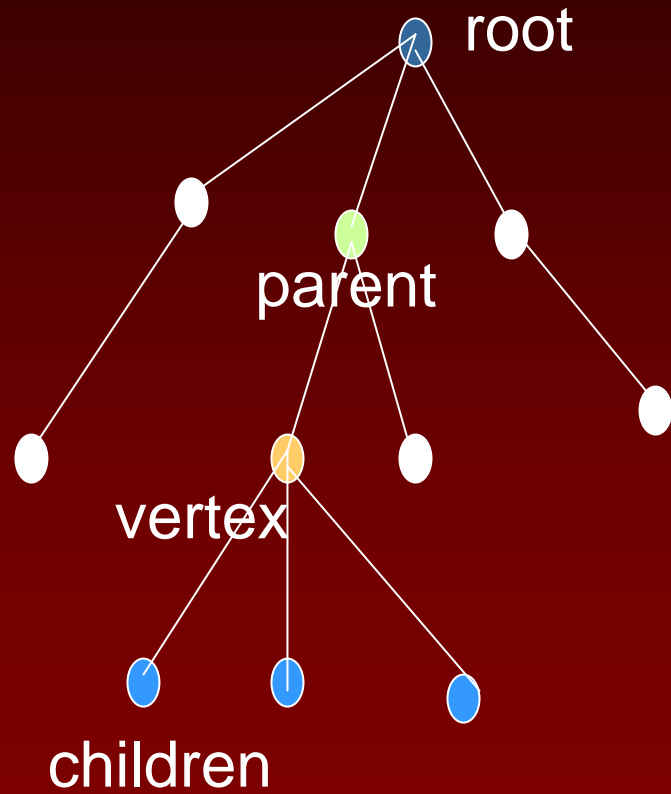

Theorem

- An undirected graph is a tree iff there is a unique simple path between any two vertices.

Definition

- A **rooted tree** is a tree in which one vertex is specified as the root & every edge is drawn away from the root

Definition

Definition

- **Root:** a vertex with no parent
- **Leaf:** a vertex with no children
- **Internal node:** vertex with children
- **Descendants:** all children and children of children
- **Ancestors:** parent and parents of parents
- **Siblings:** vertices with the same parent

Definition

- An **m-ary tree** is a rooted tree where the number of children of any internal vertex $\leq m$
- A **full m-ary tree** is an m-ary tree where the number of children of any internal vertex = m
- if $m=2$, we call it **binary tree**

Definition

- In an ordered rooted tree the children are ordered.
- For example, in an ordered binary tree, a vertex may have left child and right child

Properties

- Number of edges in a tree of size $n = n - 1$
- Any full m -ary tree with i internal vertices has $m i + 1$ vertices

Properties

A full m -ary tree with

■ *n vertices has $i = (n-1)/m$ internal and*

$l = ((m-1)n+1)/m$ leaves

■ *i internal has $n = mi+1$ vertices and*

$l = (m-1)i+1$ leaves

■ *l leaves has $n = (ml-1)/(m-1)$ vertices and*

$i = (l-1)/(m-1)$ internal
