Abstract

We investigate the inverse problem involving recovery of initial temperature from the information of final temperature profile in a disc. This inverse problem arises when experimental measurements are taken at any given time, and it is desired to calculate the initial profile. We consider the usual heat equation and the hyperbolic heat equation with Bessel operator. An integral representation for the problem is found, from which a formula for initial temperature is derived using Picard's criterion and the singular system of the associated operators.

1. Introduction

The initial inverse problems are much less encountered in the literature than the other types of inverse problems. The reason for this is that the initial condition influences the temperature distribution inside a body only for a limited time interval. This phenomenon is due to the use of the classical Fourier–Kirchhoff law that assumes the infinite velocity of heat waves. Also the initial inverse problem based on the parabolic heat equation is extremely ill-posed; see, e.g., Engl [1]. There exists another approach to this inverse problem that consists of a complete reformulation of the governing equation. The inverse problem based upon the parabolic heat equation is closely approximated by a hyperbolic heat equation; see e.g., Weber [2], and Elden [3]. This alternate formulation gives rise to an inverse problem, which is stable and well posed and thus gives more reliable results. Moreover, as we see later, the parabolic heat conduction model can be treated as limiting case of the hyperbolic model.

The need to consider the alternate formulation has some physical advantages. In many applications, one encounters the situation where the usual parabolic heat equation does not serve as a realistic model. For instance, if the speed of propagation of the thermal signal is finite, i.e., for short-pulse laser applications, then the hyperbolic differential equation correctly models the problem; see Vedavarz et al. [4] and Gratzke et al. [5] among others. We present here an inverse problem, which seeks the initial temperature distribution from a given final temperature in a disc using a parabolic as well as a hyperbolic model.

In this paper we are concerned with the study of radially symmetric solutions in a disc. The heat equation with Bessel operator possesses radially symmetric solutions in a disc, see for instance Wyld [6] and Walter [7]. We will consider hyperbolic heat equation with a small parameter and we will show that its solution approximates the solution to parabolic heat equation. The initial inverse problem in hyperbolic heat equation is stable and well-posed. Moreover, numerical methods for hyperbolic problems are efficient and accurate. We will utilize the small value of the parameter and apply WKBJ method to solve the initial inverse problem, see Bender and Orszag [8]. We will also show that by controlling the size of the parameter the solution may give some information for higher modes in case there is white Gaussian noise added to the data. In the second section we will solve the inverse problem by considering the heat equation with Bessel operator. In the third section the inverse problem in hyperbolic equation by introducing a small parameter will be solved and compared with the inverse solution of heat equation. An example will also be presented to check the validity of the inverse solution. We will perform some numerical experiments and results

of these experiments will be analysed in the fourth section. Finally in the last section results will be summarized.

2. Initial inverse problem in heat equation

We consider

$$\frac{\partial u}{\partial t}=\frac{\partial^2 u}{\partial x^2}+\frac{1}{x}\frac{\partial u}{\partial x},\quad 0<x<1, \tag{1}$$

with

$$u(1,t)=0, \tag{2}$$

and we assume the final temperature distribution

$$f(x)=u(x,T). \tag{3}$$

We want to recover the initial temperature profile

$$g(x)=u(x,0). \tag{4}$$

The boundary condition (2) can be replaced by an insulated boundary, i.e. $u_x(1,t)=0$, because it is important in some applications. All details for insulated boundary condition can be carried out similarly as described in this paper.

We assume by separation of variables, solution of the direct problem of the form

$$u(x,t)=\sum_{n=1}^{\infty} v_n(t)\phi_n(x), \tag{5}$$

The corresponding eigenvalue problem is given by

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[x\frac{\mathrm{d}\phi(x)}{\mathrm{d}x}\right]+\lambda x\phi(x)=0,\quad 0<x<1, \tag{6}$$

together with

$$\phi(1)=0. \tag{7}$$

At the singular end point $x=0$, from applications point of view, we impose a boundary condition of the form

$$\lim_{x\to 0} x\frac{\mathrm{d}\phi(x)}{\mathrm{d}x}=0. \tag{8}$$

In application to heat conduction problem, x is the radial cylindrical coordinate and condition (8) states that total heat flux through a small circle surrounding the origin vanishes, that is, there is no heat source at the origin. The independent solutions of (6) for $\lambda\neq 0$ are $J_0(\sqrt{\lambda}x)$ and $N_0(\sqrt{\lambda}x)$. But from these two independent solutions only $J_0(\sqrt{\lambda}x)$ satisfies (8). It is usual to replace (8) by the condition that the solution be finite at the origin, which has the same effect as far as selecting $J_0(\sqrt{\lambda}x)$ the only admissible solution. Now we apply condition (7), which gives rise to a sequence $\{\lambda_n\}$ of positive eigenvalues and the corresponding eigenfunctions are $J_0(\sqrt{\lambda_n}x)$. These eigenfunctions are orthogonal in the Hilbert space $H_x[0,1]$, where x is the weight function. These eigenfunctions can be orthonormalized either by Green's function method or by direct integration, the orthonormalized eigenfunctions are

$$\phi_n(x)=\frac{\sqrt{2}}{J_0'(\sqrt{\lambda_n})}J_0\left(\sqrt{\lambda_n}x\right), \tag{9}$$

where $'$ denotes the derivative with respect to x. These eigenfunctions satisfy the following condition

$$\int_0^1 x\phi_n(x)\phi_m(x)\,\mathrm{d}x=\begin{cases}0 & m\neq n,\\ 1 & m=n.\end{cases} \tag{10}$$

The eigenfunctions given by (9) are complete in $H_x[0,1]$, and therefore $g(x)\in H_x[0,1]$ can be expanded as

$$g(x)=\sum_{n=1}^{\infty} c_n\phi_n(x), \tag{11}$$

where

$$c_n=\int_0^1 \zeta\phi_n(\zeta)g(\zeta)\,\mathrm{d}\zeta. \tag{12}$$

Now by using (5), $v_n(t)$ satisfies the following initial value problem

$$\frac{\mathrm{d}v_n(t)}{\mathrm{d}t}=-\lambda_n v_n(t), \tag{13}$$

$$v_n(0)=c_n, \tag{14}$$

where we have used the following relation

$$\int_0^1 x\phi_n'(x)\phi_m'(x)\,\mathrm{d}x=\begin{cases}0 & m\neq n,\\ \lambda_n & m=n.\end{cases} \tag{15}$$

So, we can write the solution of the direct problem (1) in the form

$$u(x,t)=\sum_{n=1}^{\infty} c_n\exp[-\lambda_n t]\phi_n(x). \tag{16}$$

This represents an analytical solution to the heat equation in cylindrical coordinates, see Carslaw and Jaeger [9]. Now by applying (3), we can write

$$f(x)=\int_0^1 K(x,\zeta)g(\zeta)\,\mathrm{d}\zeta, \tag{17}$$

where

$$K(x,\zeta)=\sum_{n=1}^{\infty}\zeta\exp[-\lambda_n T]\phi_n(\zeta)\phi_n(x). \tag{18}$$

Thus the inverse problem is reduced to solving integral equation of the first kind. The singular system of the integral operator in (17) is

$$\{\exp[-\lambda_n T];\ \phi_n(x),\ \phi_n(x)\}. \tag{19}$$

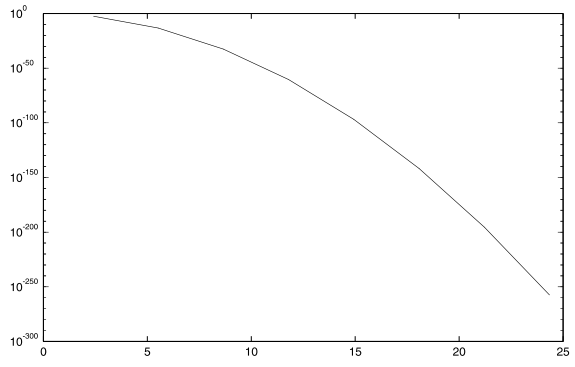

Fig. 1. First 100 singular values for $T = 1$ on a log-scale.

Now by application of Picard's theorem (see Engl [1]) the inverse problem is solvable iff

$$\sum_{n=1}^{\infty} \exp[2\lambda_n T]|f_n|^2 < \infty, \tag{20}$$

where

$$f_n = \int_0^1 \zeta \phi_n(\zeta) f(\zeta)\, \mathrm{d}\zeta, \tag{21}$$

are the classical Fourier coefficients of f. Now again by Picard's theorem, we can recover the initial profile by the following expression

$$g(x) = \sum_{n=1}^{\infty} \exp[\lambda_n T] f_n \phi_n(x). \tag{22}$$

Picard's theorem demonstrates the ill-posedness of the problem considered. If we perturb the data by setting $f^\delta = f + \delta\phi_n$ we obtain a perturbed solution $g^\delta = g + \delta\phi_n \exp[\lambda_n T]$. Hence the ratio $\|g^\delta - g\|/\|f^\delta - f\| = \exp[\lambda_n T]$ can be made arbitrarily large due to the fact that the singular values $\exp[-\lambda_n T]$ decay exponentially, see Fig. 1. The influence of errors in the data f is obviously controlled by the rate of this decay. This error can also be controlled further by choosing a small value of T, for example for $T = 1$, a small error in the nth Fourier coefficient is amplified by the factor $\exp[\lambda_n]$. So to regularize, we confine to lower modes by keeping first few terms in the series (22). This technique of truncating the series is known as truncated singular value decomposition (TSVD), see Hansen [10]. Also see [10], for a method of choosing the appropriate number of terms in the series.

3. Initial inverse problem in hyperbolic heat equation

There exists an alternate approach to the heat conduction problem [2,3], which consists of introducing a hyperbolic term with a small parameter. By controlling the size of the parameter we would like to approximate solution to the heat conduction problem. Also in some interesting situations the coefficient of the term $\partial^2 u/\partial t^2$ is small due to properties of the material [4,5]. So, we reformulate the problem as follows:

$$\epsilon \frac{\partial^2 u}{\partial t^2} + \frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + \frac{1}{x}\frac{\partial u}{\partial x}, \quad 0 < x < 1, \tag{23}$$

together with (2)–(4) and (8) and $\epsilon \to 0^+$. We impose one more condition as follows:

$$\frac{\partial u}{\partial t}(x, 0) = 0. \tag{24}$$

As before, by separation of variables, we assume solution of the form (5). In this case $v(t)$ has to solve the following initial value problem

$$\epsilon \frac{\mathrm{d}^2 v_n(t)}{\mathrm{d}t^2} + \frac{\mathrm{d}v_n(t)}{\mathrm{d}t} = -\lambda_n v_n(t), \tag{25}$$

$$v_n(0) = c_n, \tag{26}$$

$$\frac{\mathrm{d}v_n(0)}{\mathrm{d}t} = 0. \tag{27}$$

Since $\epsilon \to 0^+$, this is a singular perturbation problem. We apply WKBJ method to obtain an asymptotic representation for the solution of (25) containing parameter ϵ; the representation is to be valid for small values of the parameter. It is demonstrated in [8] that the solution stays closer to the exact solution for large values such as $\epsilon = 0.5$. The solution of (25) is given by

$$v_n(t) = \left(\frac{\epsilon\lambda_n - 1}{2\epsilon\lambda_n - 1}\right) c_n \exp[-\lambda_n t] + \left(\frac{\epsilon\lambda_n c_n}{2\epsilon\lambda_n - 1}\right) \exp\left[\lambda_n t - \frac{t}{\epsilon}\right]. \tag{28}$$

As before, we can use this solution in (5) to arrive at an integral equation of the form (17). The singular system in this case is

$$\left\{ \left(\frac{\epsilon\lambda_n - 1}{2\epsilon\lambda_n - 1}\right) \exp[-\lambda_n T] + \left(\frac{\epsilon\lambda_n}{2\epsilon\lambda_n - 1}\right) \exp\left[\lambda_n T - \frac{T}{\epsilon}\right];\ \phi_n(x),\ \phi_n(x) \right\}. \tag{29}$$

Now by Picard's theorem (see Engl [1]) the solution exists iff

$$\sum_{n=1}^{\infty} \frac{|f_n|^2}{\left[\left(\frac{\epsilon\lambda_n - 1}{2\epsilon\lambda_n - 1}\right) \exp[-\lambda_n T] + \left(\frac{\epsilon\lambda_n}{2\epsilon\lambda_n - 1}\right) \exp\left[\lambda_n T - \frac{T}{\epsilon}\right]\right]^2} < \infty, \tag{30}$$

where the Fourier coefficients f_n are given by (21). The initial profile can be recovered by the following expression

$$g(x) = \sum_{n=1}^{\infty} \frac{\phi_n(x)}{\left[\left(\frac{\epsilon\lambda_n - 1}{2\epsilon\lambda_n - 1}\right)\exp\left[-\lambda_n T\right] + \left(\frac{\epsilon\lambda_n}{2\epsilon\lambda_n - 1}\right)\exp\left[\lambda_n T - \frac{T}{\epsilon}\right]\right]}. \tag{31}$$

The solution given by (20) and (22) can be recovered by letting $\epsilon \to 0^+$ in (30) and (31), respectively.

Since the non-linear operators do not have singular values and singular function therefore we cannot apply the method to non-linear equations. For example if we consider non-linear heat equation, $u_t = (\kappa(u)u_x)_x$, then the method of approximating it with the hyperbolic model presented in this section still works but the method of singular value decomposition does not.

Example. Let us consider the initial temperature distribution of the form

$$g(x) = \frac{\sqrt{2}}{J_0'(\sqrt{\lambda_m})} J_0\left(\sqrt{\lambda_m} x\right). \tag{32}$$

First we solve the direct problems (1) and (23) together with conditions (2)–(4), (8) and (24), to find the final profiles . The Fourier coefficients corresponding to the final profiles of the parabolic and hyperbolic models, respectively, are

$$f_m = \exp\left[-\lambda_m T\right], \tag{33}$$

$$f_m = \left(\frac{\epsilon\lambda_m - 1}{2\epsilon\lambda_m - 1}\right)\exp\left[-\lambda_m T\right] + \left(\frac{\epsilon\lambda_m}{2\epsilon\lambda_m - 1}\right)\exp\left[\lambda_m T - \frac{T}{\epsilon}\right]. \tag{34}$$

Now we use the Fourier coefficients given by (33) and (34) in (22) and (31), respectively to recover the initial profile. It is clear that in both the cases the recovered initial profile is (32).

4. Numerical experiments

Now we use the final data for hyperbolic heat equation given by (34) in the parabolic model (22) and compare it with the exact initial profile for different values of the parameter. Also we use the final data for parabolic heat equation given by (33) in the hyperbolic model (31) and compare it with the exact initial profile. We consider the initial profile given by (32) for $m = 2$, also setting $T = 1$. Then we add white Gaussian noise in the data (33) and use it in the models (22) and (31) and compare it with the exact initial profile for different values of the parameter ϵ. We also consider the higher modes and see their effects on recovery of initial profile by using noisy data.

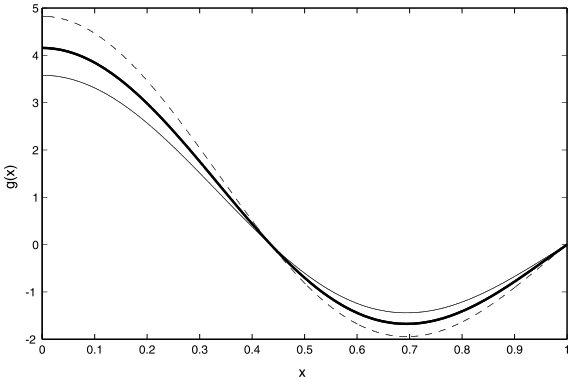

Fig. 2. The case $m = 2$, $T = 1$, $\epsilon = 0.004$.

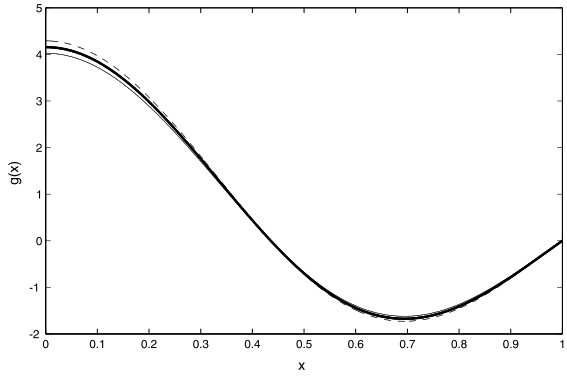

Fig. 3. The case $m = 2$, $T = 1$, $\epsilon = 0.001$.

In Figs. 2 and 3, the thick solid line represents the exact initial profile, the thin solid line and dotted line for the initial profile when (33) and (34) are used in (31) and (22), respectively.

It is evident from Figs. 2 and 3 that the solution of hyperbolic model closely approximates the heat conduction model. It approaches to the exact profile as $\epsilon \to 0^+$. Furthermore, it approaches to the exact profile from below, so it is stable.

Now we analyse the models by adding white Gaussian noise to the data. In Figs. 4–9, we use the noisy data in both parabolic and hyperbolic models and see the mean behaviour of 100 independent realizations. The noisy data used in the heat equation model (22) are represented by a dotted line and in the hyperbolic model (31) by a thin solid line and the exact initial profile by a thick solid line.

We have considered the second mode, that is, $m = 2$ in Figs. 4–6. Also we have retained first three terms ($N = 3$) in series (22) and (31). In Fig. 4, the signal to noise ratio (SNR) is equal to 620 dB (we have chosen

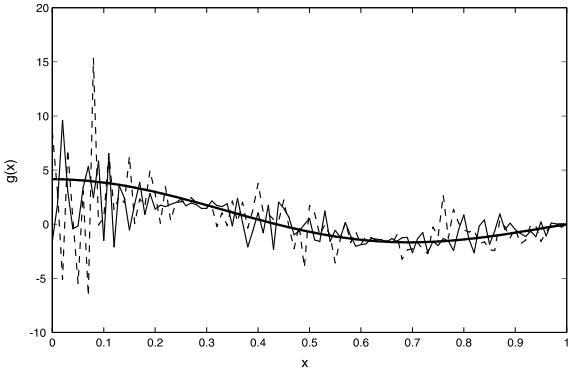

Fig. 4. The case of noisy data with SNR = 620 dB, $N = 3$, $m = 2$, $T = 1$, $\epsilon = 0.003$.

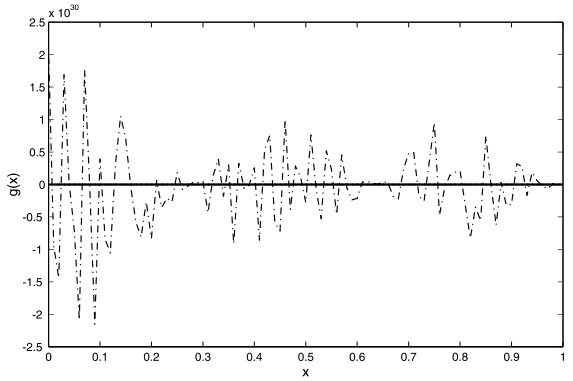

Fig. 5. The case of noisy data with SNR = 30 dB, $N = 3$, $T = 1$, $m = 2$.

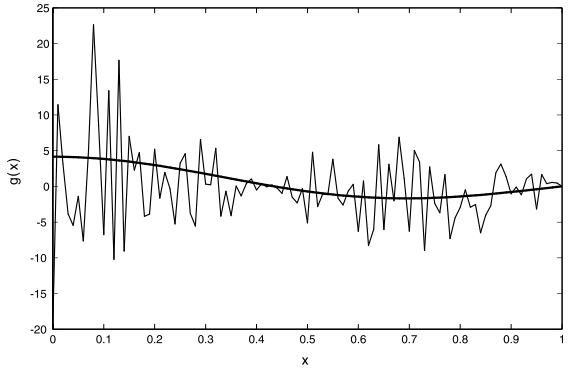

Fig. 6. The case of noisy data with SNR = 30 dB, $N = 3$, $m = 2$, $T = 1$, $\epsilon = 0.0275$.

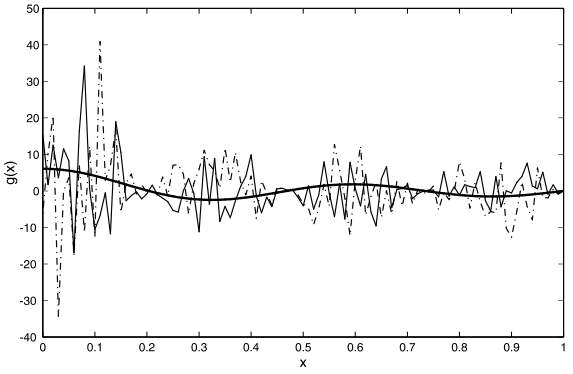

Fig. 7. The case of noisy data with SNR = 1160 dB, $N = 4$, $T = 1$, $m = 4$, $\epsilon = 0.002$.

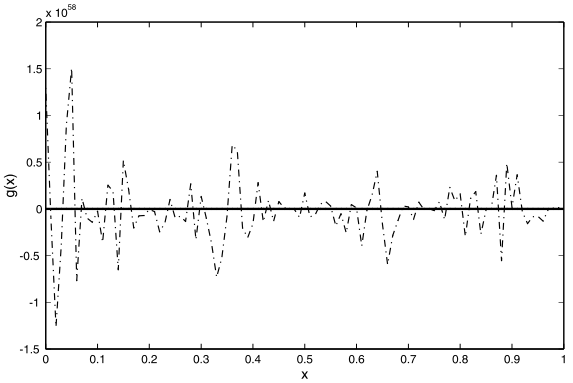

Fig. 8. The case of noisy data with SNR = 30 dB, $N = 4$, $T = 1$, $m = 4$.

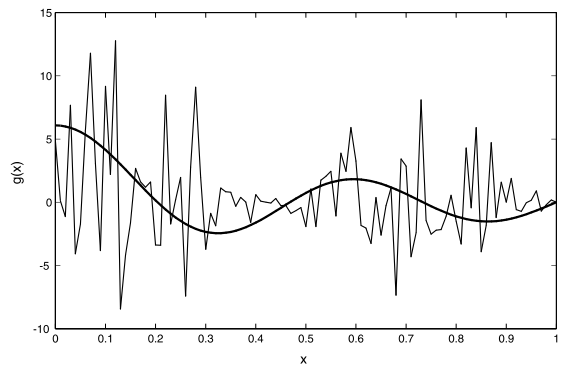

Fig. 9. The case of noisy data with SNR = 30 dB, $m = 4$, $T = 1$, $\epsilon = 0.027$.

SNR = 620 dB to ensure both the models appear clearly in the figure) and $\epsilon = 0.003$. The hyperbolic model behaves better than the parabolic model even for this low level of noise. We have increased the level of noise in

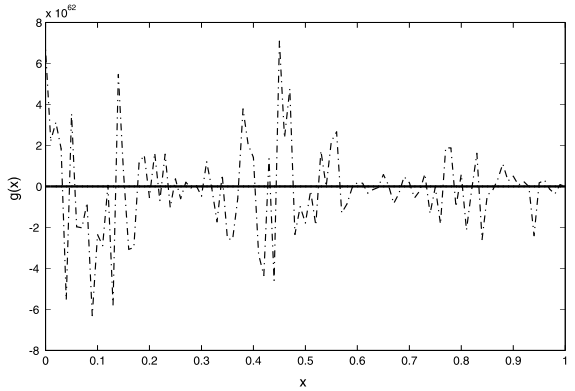

Fig. 10. The case of noisy data with SNR = 30 dB, $N = 3$, $T = 2$, $m = 2$.

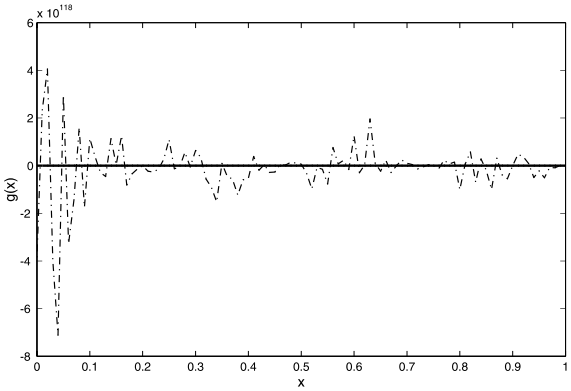

Fig. 12. The case of noisy data with SNR = 30 dB, $N = 4$, $T = 2$, $m = 4$.

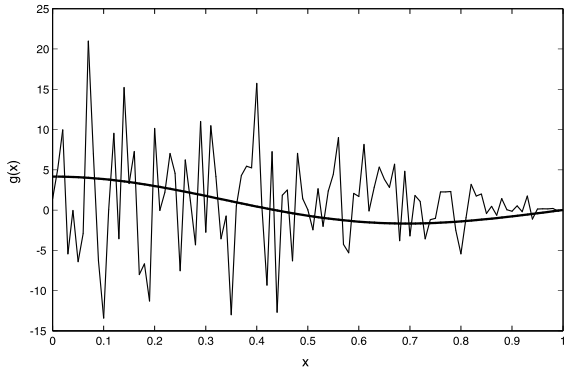

Fig. 11. The case of noisy data with SNR = 30 dB, $N = 3$, $T = 2$, $m = 2$, $\epsilon = 0.1$.

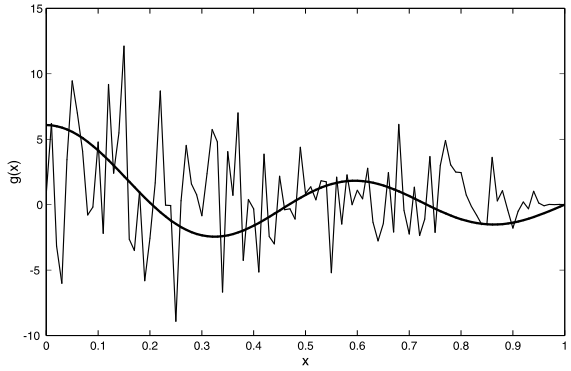

Fig. 13. The case of noisy data with SNR = 30 dB, $N = 4$, $T = 2$, $m = 4$, $\epsilon = 0.1$.

Figs. 5 and 6 to SNR = 30 dB. In Fig. 6, the approximation of exact initial profile by the hyperbolic model is demonstrated with an appropriate choice of ϵ. How to choose ϵ is discussed in the last paragraph of this section. The inherent instability of parabolic model is clear from Fig. 5 by observing the vertical axis is of order 10^{30}.

In Figs. 7–9, we have considered $m = 4$ and $N = 4$. In Fig. 7, we set SNR = 1160 dB, $\epsilon = 0.002$, and see the effects of this very low noise on both the models as compared to the exact profile. We increase SNR to 30 dB and observe the behaviour of parabolic model in Fig. 8 by noting the vertical axis is a multiple of 10^{58}. However for Hyperbolic model in Fig. 9 with SNR = dB and $\epsilon = 0.027$, some information of the initial profile may be recovered. So from above analysis of figures, we conclude that the hyperbolic model behaves much better than the parabolic model in case of noisy data. Even for lower modes, if the magnitude of noise increases, the parabolic model becomes highly unstable.

To see the effects of the size of parameter T on both models, we set $T = 2$ in Figs. 11–13. Compare Figs. 10 and 11 with Figs. 5 and 6 and Fig. 12 and 13 with Figs. 8 and 9. For parabolic model, the error is more than double. However for hyperbolic model, there is a very little degradation.

To choose ϵ, we start from a higher value of ϵ for which there is no signal appearing on the graph. We gradually reduce the size and note the values of ϵ for which the signal starts to appear. We reduce the size further and note the values of ϵ for which the signal amplifies significantly. Then we take mean of the two values of ϵ, which will give an appropriate choice of ϵ. For example, in Fig. 9, the signal starts to appear for $\epsilon = 0.03$ and it amplifies to a significant level for $\epsilon = 0.0024$. So the appropriate choice of ϵ is approximately 0.0027 and it may be refined further by checking neighbouring values of 0.0027 for which the spikes are milder. We have observed that the same procedure

of finding ϵ works for higher modes as well as for lower modes.

5. Conclusions

The inverse solution of heat conduction model is characterized by discontinuous dependence on the data. A small error in the nth Fourier coefficient is amplified by the factor $\exp[\lambda_n T]$. Thus it depends on the rate of decay of singular values and this rate of decay also depends on the size of parameter T. In order to get some meaningful information, one has to consider first few degrees of freedom in the data and has to filter out everything else depending on the rate of decay of singular values and the size of parameter T.

It is shown that a complete reformulation of the heat conduction problem as a hyperbolic equation produces meaningful results. The hyperbolic model with a small parameter closely approximates the heat conduction equation. It is also shown that in case of noisy data, the hyperbolic model approximates the exact initial profile better as compared to heat conduction model. However, in case of noisy data, the information about the initial profile cannot be recovered for higher modes by heat conduction model but in this case the hyperbolic model may give some useful information about the initial profile if the value of parameter ϵ is chosen appropriately. We have presented a method to estimate the parameter ϵ. It remains to find an analytical formula to estimate an appropriate value of the parameter ϵ which best regularizes the heat conduction model. At least our method may motivate and suggest, where to look for it.
