Revision – Fourier Transform

- A “transformation” between the time domain and the frequency domain

Time (t) **Frequency (f)**
s(t) **↔** **S(f)**

$$S(f) = \int_{-\infty}^{\infty} s(t) e^{-j2\pi ft} dt \quad \text{Fourier Transform}$$

$$s(t) = \int_{-\infty}^{\infty} S(f) e^{+j2\pi ft} df \quad \text{Inverse Fourier Transform}$$

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

2

Revision – Fourier Transform (2)

- **F.T. can be used to find the BANDWIDTH of a signal or system**
 - **Bandwidth - system:** range of frequencies passed (perhaps scaled) by system
 - **Bandwidth – signal:** range of (+ve) frequencies contained in the signal

Revision – Fourier Transform (3)

- **Remember for periodic signals (i.e. $s(t) = s(t+T)$ where T is the period) → Fourier Series expansion:**

$$s(t) = \frac{A_0}{2} + \sum_{n=1}^{\infty} [A_n \cos(2\pi n f_0 t) + B_n \sin(2\pi n f_0 t)]$$

$$A_0 = \frac{2}{T} \int_0^T s(t) dt \quad B_n = \frac{2}{T} \int_0^T s(t) \sin(2\pi n f_0 t) dt$$

$$A_n = \frac{2}{T} \int_0^T s(t) \cos(2\pi n f_0 t) dt$$

f_0 is the fundamental frequency and is equal to $1/T$

Revision – Fourier Transform (4)

- Famous pairs – rectangular pulse ($A = T = 1$)

$$s(t) = \Pi(t/T)$$

$$S(f) = AT \frac{\sin(\pi f T)}{\pi f T}$$

$$S(f) = AT \text{ for } f = 0$$

$$= 0 \text{ for } f = n/T; n = \pm 1, 2, \dots$$

9/23/2003

5

Revision – Fourier Transform (5)

- Famous pairs – Raised Cosine pulse ($A = T = 1$), as a function of α

$$s(t) = \frac{(2A)}{T} \frac{\cos(2\pi\alpha t) \sin(2\pi/T)}{1 - (4\alpha t)^2}$$

$$S(f) = \begin{cases} A & |f| > \frac{1}{T} - \alpha \\ A \cos^2\left(\frac{\pi}{4\alpha}\left(|f| - \frac{1}{T} + \alpha\right)\right) & \frac{1}{T} - \alpha < |f| < \frac{1}{T} + \alpha \\ 0 & |f| > \frac{1}{T} + \alpha \end{cases}$$

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

6

Revision – Fourier Transform (6)

- **Raised Cosine Pulse: $0 < \alpha < 1/T$**
- **Note that $s(t) = 0$ for $t = nT/2$ where $n = +/- 1, 2, \dots$**
 - **Very good for forming pulses**
 - **ZERO ISI for ideal situation**
- **BW for $s(t) = 1/T + \alpha$**
 - **Maximum = $2 \times 1/T$ (for $\alpha = 1/T$)**
 - **Minimum = $1/T$ (for $\alpha = 0$)**

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

7

Revision – Fourier Transform (7)

- **Matlab code:**

```
clear all % clear all variables

A = 1;
T = 1;
alphas = [0 0.5 1];

for k = 1:length(alphas)
    alpha = alphas(k);

    t = -2:0.01:2; % define the time axis
    s_t(k,:) = ((2*A)/T) * (cos(2*pi*alpha*t)./ ...
        (1-(4*alpha*t).^2)) .* (sin(2*pi*t/T)./ ...
        (2*pi*t/T)); % define s(t)

    f = -2.5:0.05:2.5; % define the freq axis
    S_f(k,:) = zeros(size(f));
    i = find(abs(f) <= (1/T-alpha));
    S_f(k,i) = A;
    i = find((abs(f) <= (1/T+alpha)) & ...
        (abs(f) > (1/T-alpha)));
    S_f(k,i) = A*(cos(pi/(4*alpha)* ...
        (abs(f(i))-1/T+alpha)).^2); % define S(f)
end

figure(1);
plot(t, s_t); % plot s(t)
title('raised cosine pulse - A = T = 1');
xlabel('time - t');
ylabel('s(t)');
legend('alpha = 0', 'alpha = 0.5', 'alpha = 1.0');
axis([-2 2 -0.5 2.2]);
grid

figure(2);
plot(f, S_f); % plot S(f)
title('Raised Cosine function - A = T = 1');
xlabel('frequency - f');
ylabel('S(f)');
legend('alpha = 0', 'alpha = 0.5', 'alpha = 1.0');
axis([-2.5 2.5 0 1.2]);
grid
```

9/23/2003

8

Signals and Systems

- **For linear Systems:**
 - **$h(t)$ is the system's impulse response – i.e. $s_o(t) = h(t)$ when $s_i(t) = \delta(t)$**
 - **$S_i(t)$ is system input signal**
 - **$S_o(t)$ is system output signal**

$$s_o(t) = \int_{-\infty}^{\infty} s_i(\tau)h(t-\tau)d\tau$$

$$s_o(t) = s_i(t) * h(t)$$

$$S_o(f) = S_i(f)H(f)$$

A good introduction into linear systems is found at http://www.ece.utexas.edu/~bevans/courses/ee313/lectures/04_Convolution/lecture4.pdf

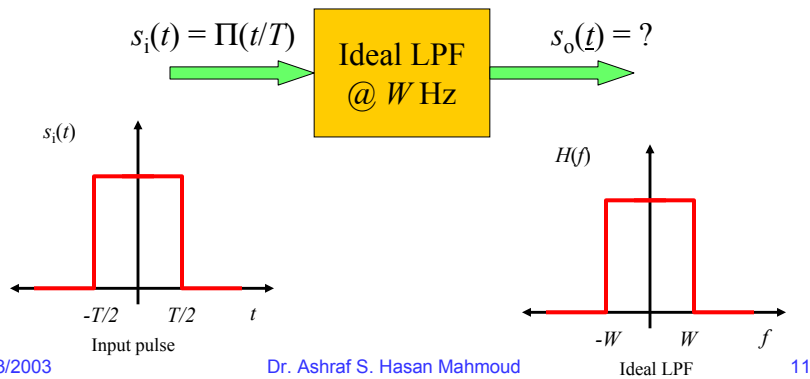

Signals and Systems (2)

- **System bandwidth is determined by examining the Fourier transfer of the system function $h(t)$, $H(f)$**
- **Example (transmission) systems:**

Signals and Systems - Example

- **Ideal Low Pass Filter – find the output signal for rectangular input pulse?**

Signals and Systems - Example

- The input signal $s_i(t)$ is given by:

$$s_i(t) = \begin{cases} A & |t| \leq T/2 \\ 0 & \text{otherwise} \end{cases}$$

- Where as its Fourier transform $S_i(f)$ is given by (note that $s_i(t)$ contains all frequencies from 0 till ∞ - refer to Fourier transform of rectangular pulse):

$$S_i(f) = AT \frac{\sin(\pi fT)}{\pi fT} \quad \text{for all } f$$

- The Fourier transform of the system impulse response, $H(f)$ is given by (note this transmission system limits frequencies to at most W Hz):

$$H(f) = \begin{cases} 1 & |f| \leq W \\ 0 & \text{otherwise} \end{cases}$$

Signals and Systems - Example

- Therefore the Fourier transform of the output signal is given by:
- $|S_o(f)| = |S_i(f)| \times |H(f)|$

$$\begin{aligned}
 & \sin(\pi fT) \\
 &= AT \frac{\sin(\pi fT)}{\pi fT} \quad \text{for } |f| < W \\
 &= 0 \quad \text{otherwise}
 \end{aligned}$$

(note the output signal has frequencies up to W Hz only)

Signals and Systems - Example

- To find the output signal $s_o(t)$, one has to use the inverse Fourier transform on $S_o(f)$
- As the BW of the system is increased, the output signal approaches a rectangular pulse (copy of input)

Exercise:

Try to apply the inverse F.T integral to obtain an analytical form of the signal $s_o(t)$ as a function of W and T .

Baseband vs. Bandband

- **Baseband Signal:**
 - Spectrum not centered around non zero frequency
 - May have a DC component
- **Bandpass Signal:**
 - Does not have a DC component
 - Finite bandwidth around or at f_c

Modulation

- **Is used to shift the frequency content of a baseband signal**
 - **Basis for AM modulation**
 - **Basis for Frequency Division Multiplexing (FDM)**

Modulation

- Consider the signal $s(t)$,
 $s_m(t) = s(t) \times \cos(2\pi f_c t)$
 The spectrum for $s_m(t)$ is given by

$$S_m(f) = \frac{1}{2} \times \{S(f-f_c) + S(f+f_c)\}$$

Modulation – Txer/Rxer

- At the receiver side:
 $s_d(t) = s_m(t) \times \cos(2\pi f_c t)$
 $= s(t) \times \cos(2\pi f_c t) \times \cos(2\pi f_c t)$
 $= \frac{1}{2} s(t) + \frac{1}{2} s(t) \times \cos(2\pi 2f_c t)$

$\underbrace{\hspace{10em}}_{\text{desired term}}$
 $\underbrace{\hspace{10em}}_{\text{undesired term – signal centered around } 2f_c \text{ filtered out using the LPF}}$

Nyquist Bandwidth

- For a noiseless channels of bandwidth B , the maximum attainable bit rate (or capacity) is given by

$$C = 2B \log_2(M)$$

Where M is the size of the signaling set

Shannon Capacity

- Capacity of a channel of bandwidth B , in the presence of noise is given by

$$C = B \log_2(1 + \text{SNR})$$

where SNR is the ratio of signal power to noise power – a measure of the signal quality

Eb/No Expression

- An alternative representation of SNR
- Consider the bit stream shown in figure – for bit of rate R, then each bit duration is equal to $T_b = 1/R$ seconds
- Energy of signal for the bit duration is equal to $A^2 \times T_b$, where its power is equal to bit energy / T_b or A^2 .
- Noise power is equal to $N_0 \times B$ (refer to thermal noise section)
- Hence, SNR is given by signal power / noise power or

$$SNR = \frac{\text{signal power}}{N_0 B} = \frac{E_b}{N_0} \times \frac{R}{B}$$

- One can also write

$$\left(\frac{E_b}{N_0} \right)_{dB} = \text{Signal Power (dBW)} - 10 \log R - 10 \log k - 10 \log T$$

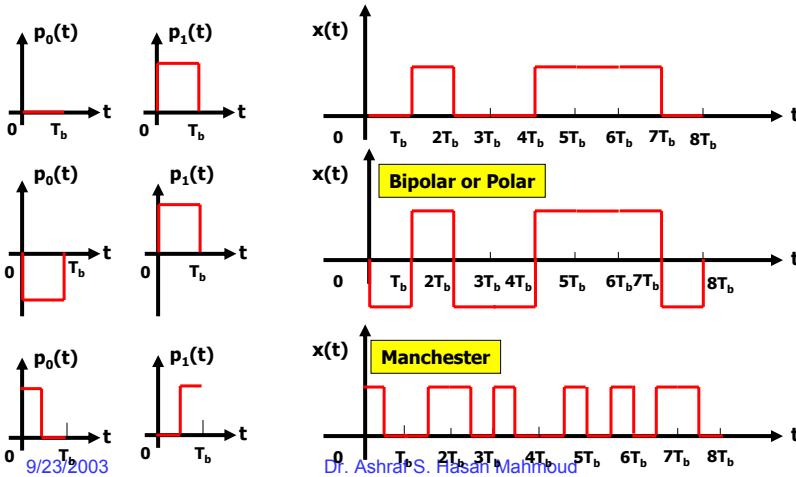

Signal Elements or Pulses

- Unit of transmission – repeated to form the overall signal
- *Shape* of pulse determines the bandwidth of the transmitted signal
- Digital data is mapped or encoded to the different pulses or units of transmission
- Baud/Modulation or Symbol Rate (R_s)
 - The bit rate $R_b = R_s \log_2(M)$
- Please refer to earlier examples of pulses and the corresponding BW

Signal Elements or Pulses

Definitions of Pulses Encoded Signal: 0 1 0 0 1 1 1 0

Examples of Digital Signaling

Signal Elements or Pulses

Pluses Definitions Encoded Signal: 0 1 0 0 1 1 1 0

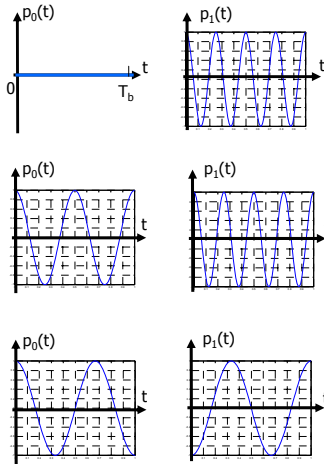

Example of Digital Signaling

- Note that each symbol or pulse carries 2 bits
- Symbol duration is $T_s = 2T_b$
- Bit rate R equal to $1/T_b$
- Symbol rate or *baud rate* R_s equal to $1/T_s \rightarrow R = 2R_s$
- In general to encode n bits per pulse, you need 2^n pulses

Signal Elements or Pulses

Definitions of Pulses

9/23/2003

Encoded Signal:

Dr. Ashraf S. Hasan Mahmoud

Example of Analog Signaling

25

Digital Signal Encoding Formats

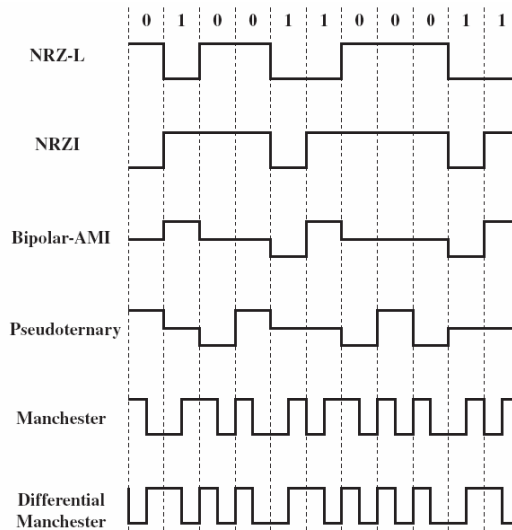

- **Nonreturn to Zero-Level (NRZ-L)**
 - 0 = high level
 - 1 = low level
- **Nonreturn to Zero Inverted (NRZI)**
 - 0 = no transition at beginning of interval
 - 1 = transition at beginning of interval
- **Bipolar-AMI**
 - 0 = no line signal
 - 1 = +ve or -ve level; alternating successive ones
- **Pseudoternary**
 - 0 = +ve or -ve level; alternating for successive ones
 - 1 = no line signal
- **Doubinary**
 - 0 = no line signal
 - 1 = +ve or -ve level; depending on number of separating 0s (even – same polarity, odd – opposite polarity)
- **Manchester**
 - 0 = transition from high to low in middle of interval
 - 1 = transition from low to high in middle of interval
- **Differential Manchester: Always transition in middle of interval**
 - 0 = transition at beginning of interval
 - 1 = no transition at beginning of interval

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

26

Digital Signal Encoding Formats

Spectrum Characteristics of Digital Encoding Schemes

Asynchronous Data Transmission

- **Digital Info:**
 - **Bits**
 - **Characters**
 - **Packets**
 - **Messages or files**
- **Serial vs. Parallel character**

Asynchronous Transmission

- Exploits: Rx-er can remain for short period in synch with Tx-er
- Used for short stream of bits – data transmitted one character (5 ~ 8 bits) at a time
- Synchronization is needed to be maintained for the length of short transmission
- Character is delimited (start & end) by known signal elements: start bit – stop element
- Rx-er re-synchs with the arrival of new character

Asynchronous Transmission

- Simple / Cheap
- Efficiency: transmit 1 start bit + 8 bit of data + 2 stop bits → Efficiency = $8/11 = 72\%$ (or overhead = $3/11 = 28\%$)
- Good for data with large gaps (e.g. keyboard, etc)

S1: receiver in idle state

S2: receiver is receiving character

(a) Character format

(b) 8-bit asynchronous character stream

Asynchronous Serial Data Tx-er and Rx-er

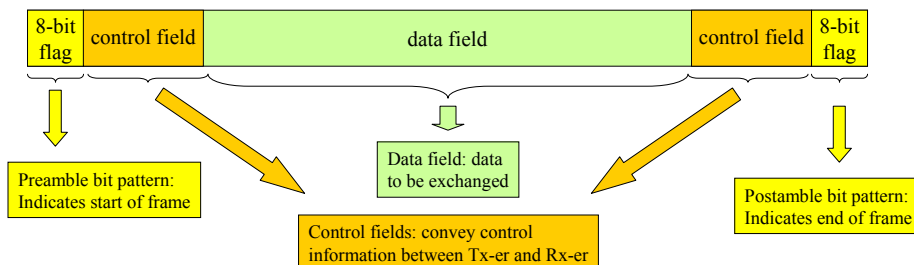

- Refer to figure 2.22

Synchronous Data Transmission

- Two ends remain in sync for significant period of time
- Use of SYNC or PREAMBLE characters
- Noise + Data = may create another SYNC character → frame split
 - Solution – use two SYNC characters
- Rx-er must buffer incoming frames and search for SYNC character(s)

Synchronous Frame Format

- Typical Frame Structure

- For large data blocks, synchronous transmission is far more efficient than asynchronous:
 - E.g. HDLC frame (to be discussed in Chapter 7): 48 bits are used for control, preamble, and postamble – if 1000 bits are used for data → efficiency = 99.4% (or overhead = 0.6%)

Interfacing

- Data Terminal Equipment (DTE): terminals or computers
- Data Circuit Equipment (DCE): modem
- Two DCEs exchanging data on behalf of DTEs must use exact same protocol

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

35

DTE-DCE Interface Definition

- Mechanical: physical specification of connection – type, dimensions, location of pins, etc
- Electrical: voltage levels and timing signals used
- Functional: specify functions that are performed for circuits – rx circuit, tx circuit, etc.
- Procedural: specification of sequence of event for transmitting data based on functional specification
- Two examples:
 - V.24/EIA-232-F, and
 - ISDN physical interface

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

36

V.24/EIA-232-F - Procedural Specification – Examples

- Example: Two terminals connected back-to-back through the V.24 interface BUT with no DCEs
- This is referred to as the NULL modem connection
- For short distance connections

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

Error Control

- Error Detection
 - Parity Checks
 - Cyclic Redundancy Check (CRC)
- For a channel of bit error rate (or BER) of P , the probability of m bits in error in a block of n bits ($m \leq n$) is given by

$$\binom{n}{m} p^m (1-p)^{n-m}$$

or

$$\frac{n!}{(n-m)!m!} p^m (1-p)^{n-m}$$

The above simple formula assumes iid error probability across all bits in block – How realistic is that?

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

38

Error Control (2)

- The probability the frame or block is correct is given by

$$(1-p)^n$$

Therefore the probability, the frame is in error (one or more bits in error) is given by

$$1-(1-p)^n$$

The above quantity is referred to as FER

Error Control - Example

- Consider a channel with BER = 10^{-3} , for a block (packet of $n = 100$ bits), the probability of having one bit in error is equal to

$$100 \times P \times (1-P)^{99} = 9 \times 10^{-2}$$

While the probability of having 4 bits in error is equal to

$$(100 \text{ choose } 4) \times P^4 \times (1-P)^{96} = 3.6 \times 10^{-6}$$

The probability that the frame is erroneous is equal to

$$(1-P)^{100} = 0.905 \rightarrow \text{i.e. } \sim 91\% \text{ of the time the frame is in error!!}$$

Error Control – Example (2)

- Relation between block size (n) and frame error rate (FER)

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

41

Simple Parity Check

- Add one extra bit for each character such that:
 - Even Parity: no of 1s even
 - Odd Parity: no of 1s odd
- Simple
- Can not detect even no of errors in character
- Adding one extra bit to a group of n bits →
Excess redundancy = $1/(n+1)$

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

42

VRC/LRC Parity Check

- Extension of simple parity: Vertical Redundancy Check (VRC) and Longitudinal Redundancy Check (LRC)

	Original data to send								
Char 1	1	0	0	1	1	0	0	0	1
Char 2	0	1	1	1	0	1	0	1	1
Char 3	1	1	0	0	1	1	0	0	0
Char 4	1	0	0	0	1	0	0	0	0
Char 5	0	1	0	0	1	1	1	0	0
Checking char	1	1	1	0	0	1	1	1	0

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

43

VRC/LRC Parity Check (2)

- Can detect all odd errors – same as the simple parity check
- Can detect any combination of even error in characters that DO NOT result in even number of errors in a column
- Excess Redundancy: $14/(40+14) = 0.26$
- There could be undetected errors – How?

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

44

Cyclic Redundancy Check (CRC)

Processing: compute FCS (for some given an $n+1$ bit polynomial P)

$k+n$ bit frame to be transmitted = T

- Modulo 2 arithmetic is used to generate the FCS:
 - $0 \pm 0 = 0; 1 \pm 0 = 1; 0 \pm 1 = 1; 1 \pm 1 = 0$
 - $1 \times 0 = 0; 0 \times 1 = 0; 1 \times 1 = 1$

CRC – Mapping Binary Bits into Polynomials

- Consider the following k -bit word or frame and its polynomial equivalent:

$$b_{k-1} b_{k-2} \dots b_2 b_1 b_0 \rightarrow b_{k-1}x^{k-1} + b_{k-2}x^{k-2} + \dots + b_1x^1 + b_0$$

where b_i ($k-1 \leq i \leq 0$) is either 1 or 0

CRC – Mapping Binary Bits into Polynomials- Examples

- Example1: an 8 bit word $M = 11011001$ is represented as $M(x) = x^7+x^6+x^4+x^3+1$

- Example2: What is $x^4M(x)$ equal to?

$x^4M(x) = x^4(x^7+x^6+x^4+x^3+1) = x^{11}+x^{10}+x^8+x^7+x^4$, the equivalent bit pattern is 110110010000 (i.e. four zeros added to the right of the original M pattern)

- Example3: What is $x^4M(x) + (x^3+x+1)$?

$x^4M(x) + (x^3+x+1) = x^{11}+x^{10}+x^8+x^7+x^4 + x^3+x+1$, the equivalent bit pattern is 110110011011 (i.e. pattern 1011 = x^3+x+1 added to the right of the original M pattern)

CRC Calculation

- $T = (k+n)$ -bit frame to be tx-ed, $n < k$
- $M = k$ -bit message, the first k bits of frame T
- $F = n$ -bit FCS, the last n bits of frame T
- $P =$ pattern of $n+1$ bits (a predetermined divisor)

$T = (n+k)$ -bit frame

P =(n+1) bit divisor

Note:

- $T(x)$ is the polynomial (of $k+n-1$ st degree or less) representation of frame T
- $M(x)$ is the polynomial (of $k-1$ st degree or less) representation of message M
- $F(x)$ is the polynomial (of $n-1$ st degree or less) representation of FCS
- $P(x)$ is the polynomial (of n th degree or less) representation of the divisor P
- $T(x) = X^n M(x) + F(x)$ – refer to example 3 on previous slide

CRC Calculation (2)

- Design: frame T such that it divides the pattern P with no remainder?
- Solution: Since the first component of T, M, is the data part, it is required to find F (or the FCS) such that T divides P with no remainder

Using the polynomial equivalent:

$$T(x) = X^n M(x) + F(x)$$

One can show that $F(x) = \text{remainder of } x^n M(x) / P(x)$

i.e if $x^n M(x) / P(x)$ is equal to $Q(x) + R(x)/P(x)$, then $F(x)$ is set to be equal to $R(x)$.

Note that:

Polynomial of degree $k+n$

----- = polynomial of degree k + remainder polynomial of degree n or less

Polynomial of degree n

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

49

CRC Calculation - Procedure

- 1. Shift pattern M n bits to the left**
- 2. Divide the new pattern $2^n M$ by the pattern P**
- 3. The remainder of the division R (n bits) is set to be the FCS**
- 4. The desired frame T is $2^n M$ plus the FCS bits**

Note:

$2^n M$ is the pattern resulting from shifting the pattern M n bits to the left. In other words, the polynomial equivalent of the pattern $2^n M$ is $x^n M(x)$

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

50

CRC Calculation – Example

- Message $M = 1010001101$ (10 bits) $\rightarrow k = 10$
 Pattern $P = 110101$ (6 bits – note 0^{th} and n^{th} bits are 1s)
 $\rightarrow n + 1 = 6 \rightarrow n = 5$

Find the frame T to be transmitted?

- Solution:

Size of $M = k$
 Size of $P = n+1$
 Size of R or $FCS = n$
 Size of $T = n+k$

• FCS = R is equal to 01110
 • Frame $T = 101000110101110$
 • As an exercise, verify that T divided by P has no remainder

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

51

CRC – Receiver Procedure

- Tx-er transmits frame T
- Channel introduces error pattern E
- Rx-er receives frame $T_r = T \oplus E$ (note that if $E = 000..000$, then T_r is equal to T , i.e. error free transmission)
- T_r is divided by P , Remainder of division is R
- if R is ZERO, Rx-er assumes no errors in frame; else Rx-er assumes erroneous frame
- If an error occurs and T_r is still divisible by $P \rightarrow$ UNDETECTABLE error (this means the E is also divisible by P)

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

52

53

CRC – Receiver Circuit

- Tx-er transmits frame T

Figure 7.7 General CRC Architecture to Implement Divisor $1 + A_1X + A_2X^2 + \dots + A_{n-1}X^{n-1} + X^n$

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

54

Sliding Window Protocol

- Stop-and-Wait can be very inefficient when $a > 1$
- Protocol:
 - Assumes full duplex line
 - Source A and Destination B have buffers each of size W frames
 - For k -bit sequence numbers:
 - Frames are numbered: $0, 1, 2, \dots, 2^k-1, 0, 1, \dots$ (modulo 2^k)
 - ACKs (RRs) are numbered: $0, 1, 2, \dots, 2^k-1, 0, 1, \dots$ (modulo 2^k)
 - A is allowed to transmit up to W frames without waiting for an ACK
 - B can receive up to W consecutive frames
 - ACK J (or RR J), where $0 \leq J < 2^k$, sent by B means B has received frames up to frame $J-1$ and is ready to receive frame J
 - B can also send RNR J : B has received all frames up to $J-1$ and is not ready to receive any more
- Window size, W can be less or equal to 2^k-1

Go-Back-N ARQ

- Based on the sliding-window flow control procedure
- If the i^{th} frame is lost or deemed lost (i.e. $i+1^{\text{st}}$ is received before the i^{th} frame), the i^{th} frame and all subsequent frames are retransmitted

Selective-Reject ARQ

- In contrast to Go-Back-N, the only frames retransmitted are those that receive –ve ACK (called SREJ) or those that time out
- More efficient:
 - Rx-er must have large enough buffer to save *post*-SREJ frames
 - Buffer manipulation – re-insertion of out-of-order frames

Window Size for Selective-Reject ARQ – Why?

- Window size: should less or equal to half range of sequence numbers
 - For n-bit sequence numbers, Window size is $\leq 2^{n-1}$ (remember sequence numbers range from 0,1, ..., 2^n-1)
- Why? See next example

Go-Back-N/Selective- Reject ARQ Examples

- With Go-back-N frames 4,5 and 6 are retransmitted
- With Selective-Reject only frame 4 is retransmitted

What is MULTIPLEXING?

- A generic term used where more than one application or connection share the capacity of one link
- Why?
 - To achieve better utilization of resources

9/23/2003

Frequency-Division Multiplexing - Transmitter

- $m_i(t)$: analog or digital information
- Modulated with subcarrier $f_i \rightarrow s_i(t)$
- $m_b(t)$ composite baseband modulating signal
- $m_b(t)$ modulated by $f_c \rightarrow$ The overall FDM signal $s(t)$

(a) Transmitter

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

Spectrum function of composite baseband modulating signal $m_b(t)$

Frequency-Division Multiplexing - Receiver

- $m_b(t)$ is retrieved by demodulating the FDM signal $s(t)$ using carrier f_c
- $m_b(t)$ is passed through a parallel bank of bandpass filters – centered around f_i
- The output of the i^{th} filter is the i^{th} signal $s_i(t)$
- $m_i(t)$ is retrieved by demodulating $s_i(t)$ using subcarrier f_i

65

Synchronous Time-Division Multiplexing - Transmitter

- Digital sources $m_i(t)$ – usually buffered
- A scanner samples sources in a cyclic manner to form a frame
- $m_c(t)$ is the TDM stream or frame → frame structure is fixed
- Frame $m_c(t)$ is then transmitted using a modem → resulting analog signal is $s(t)$

(a) Transmitter

(b) TDM Frames

Fixed assignments – slot left empty if no data
No address requirement
Bit stuffing

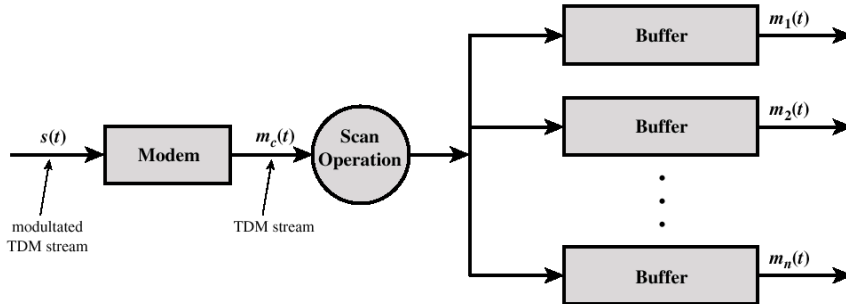

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

66

Synchronous Time-Division Multiplexing - Receiver

- TDM signal $s(t)$ is demodulated \rightarrow result is TDM digital frame $m_c(t)$
- $m_c(t)$ is then scanned into n parallel buffers;
- The i^{th} buffer correspond to the original $m_i(t)$ digital information

67

Statistical Time-Division Multiplexing

- **Dynamic and on-demand allocation of time slots**

9/23/2003

Dr. Ashraf S. Hasan Mahmoud

68

Statistical Time-Division Multiplexing Frame Format

- Clearly, the aim of statistical TDM is increase efficiency by not sending empty slots
- But it requires overhead info to work:
 - Address field
 - Length field

(a) Overall frame

(b) Subframe with one source per frame

(c) Subframe with multiple sources per frame

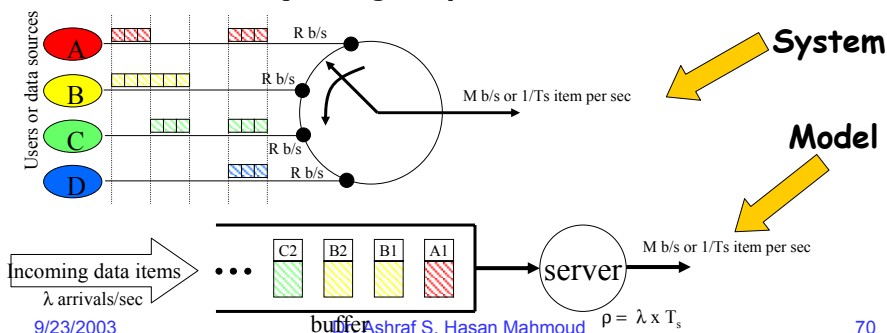

9/23/2003

Statistical Time-Division Multiplexing – Modeling

- Data items (bits, bytes, etc) are generated at any time – source may be intermittent (bursty) not constant
- R b/s is the peak rate for single source
 - αR b/s is the average rate for single source ($0 \leq \alpha \leq 1$)
- The *effective* multiplexing line rate is M b/s
- Each data item requires T_s sec to be served or tx-ed
- Data items may accumulate in buffer before server is able to transmit them \rightarrow Queuing delay
